

Stereo Correspondences

Computer Vision
CSCI 4420U

Faisal Qureshi

Why Stereo Vision?

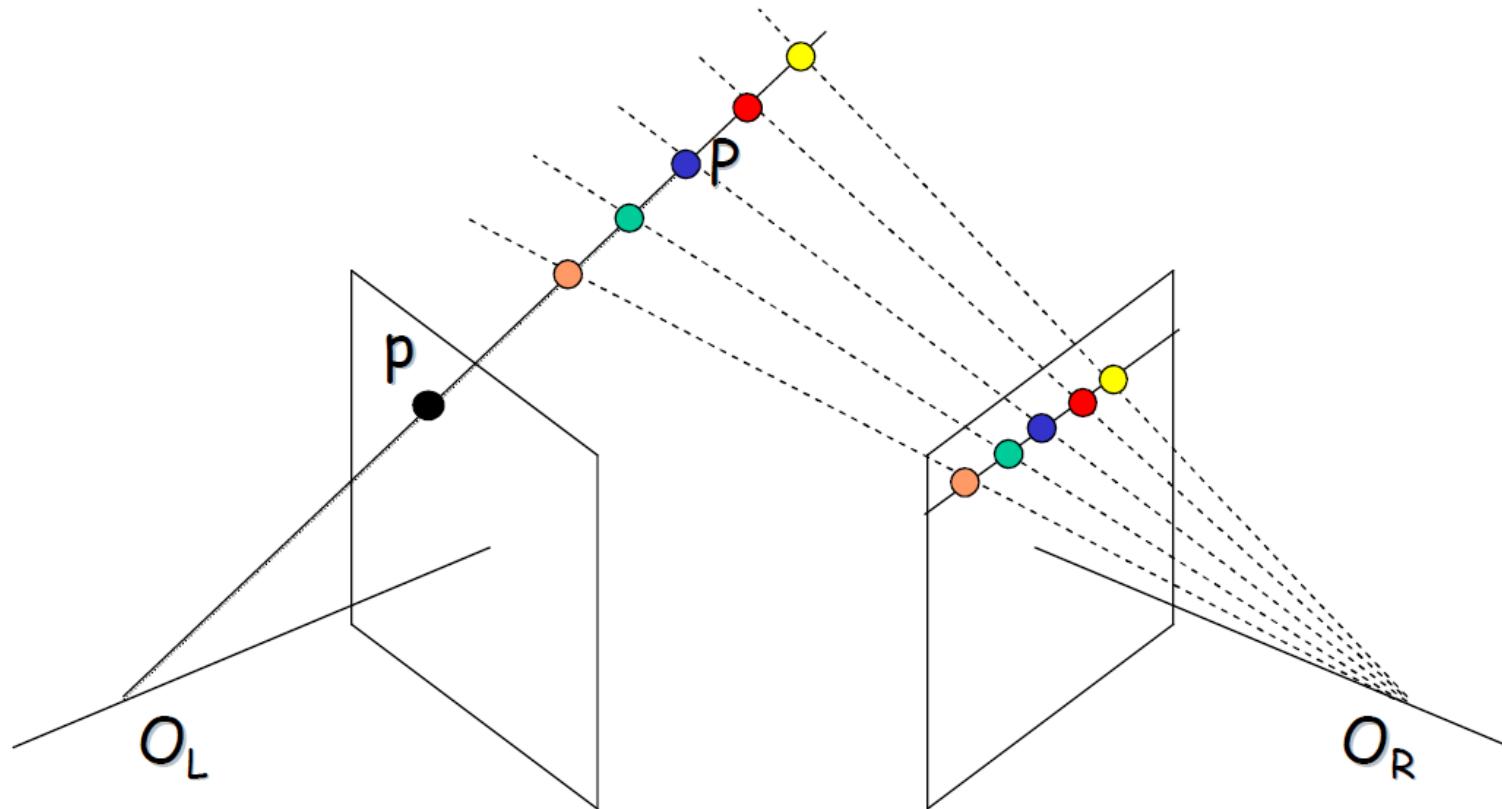

$$x = f \frac{X}{Z} = f \frac{kX}{kZ}$$

$$y = f \frac{Y}{Z} = f \frac{kY}{kZ}$$

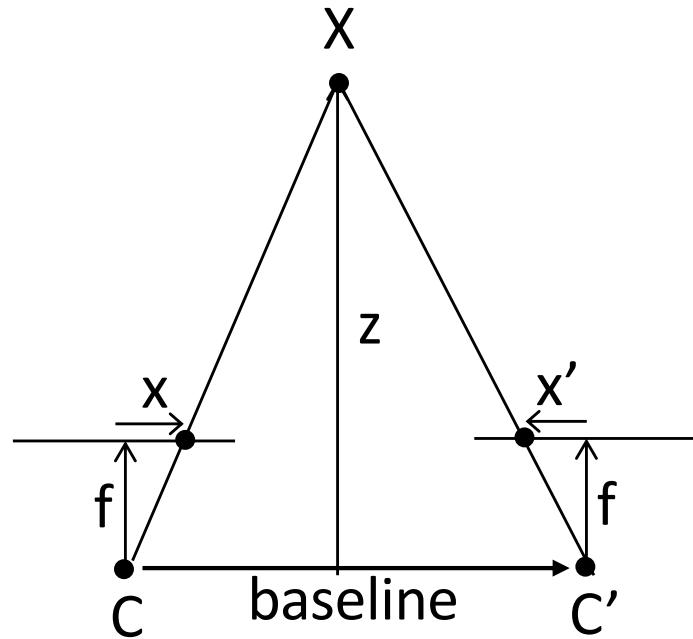

Fundamental Ambiguity:
Any point on the ray OP has image p

Why Stereo Vision?

A second camera can resolve the ambiguity,
enabling measurement of depth via triangulation.

Depth from disparity

$$(X - X') / f = \text{baseline} / z$$

$$X - X' = (\text{baseline} * f) / z$$

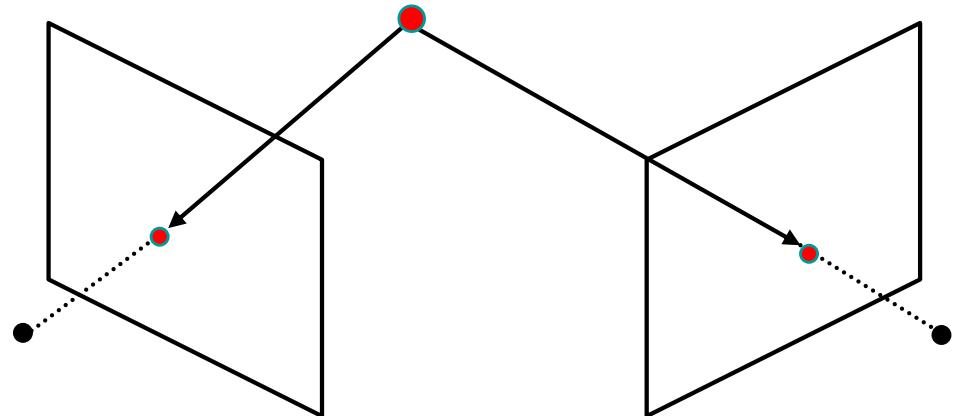

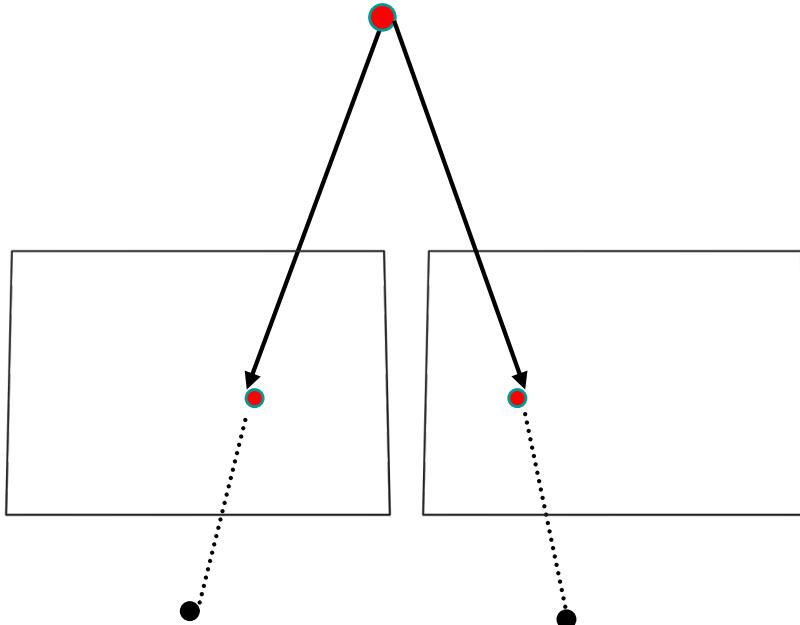

$$z = (\text{baseline} * f) / (X - X')$$

Outline

- Human stereopsis
- Stereograms
- Epipolar geometry and the epipolar constraint
 - Case example with parallel optical axes
 - General case with calibrated cameras

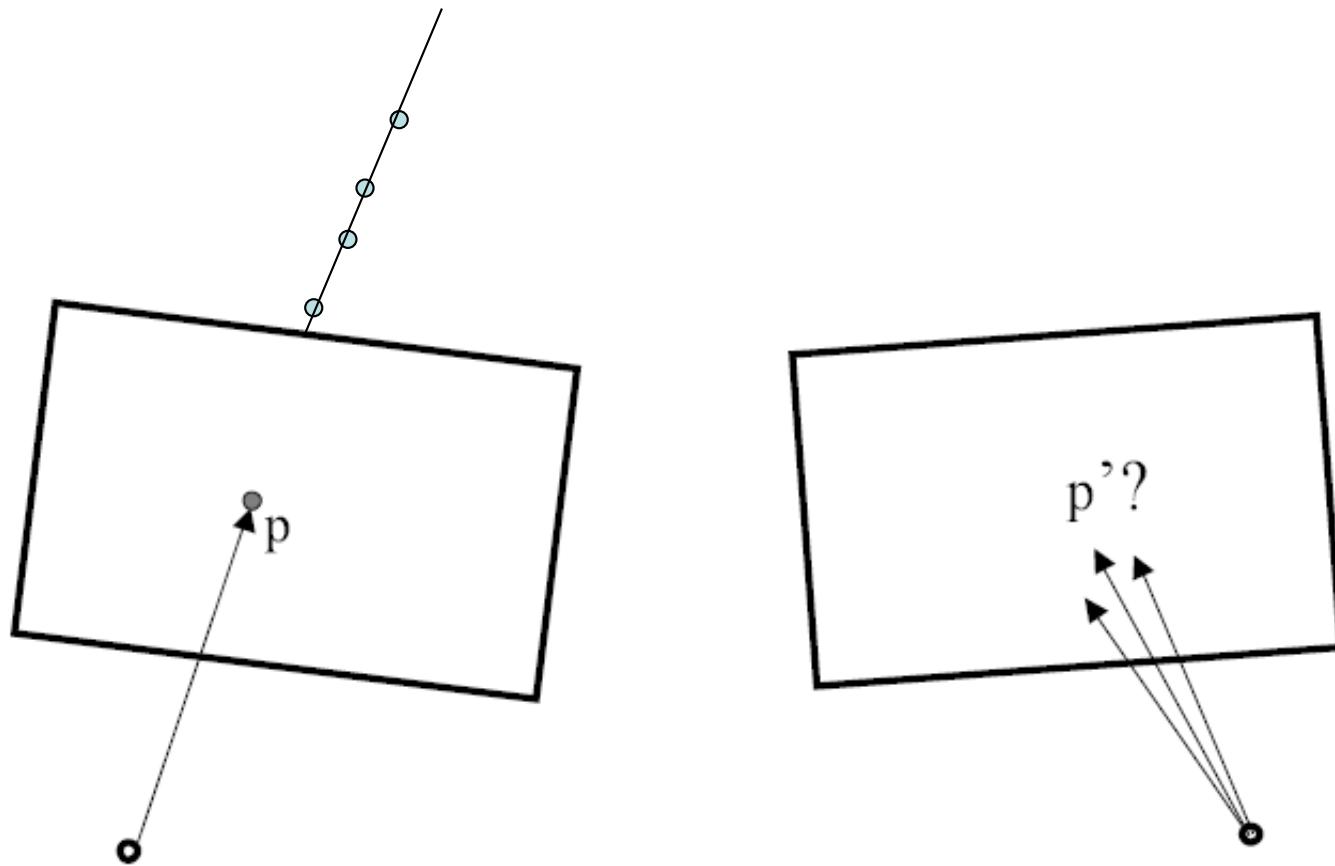

General case, with calibrated cameras

- The two cameras need not have parallel optical axes.

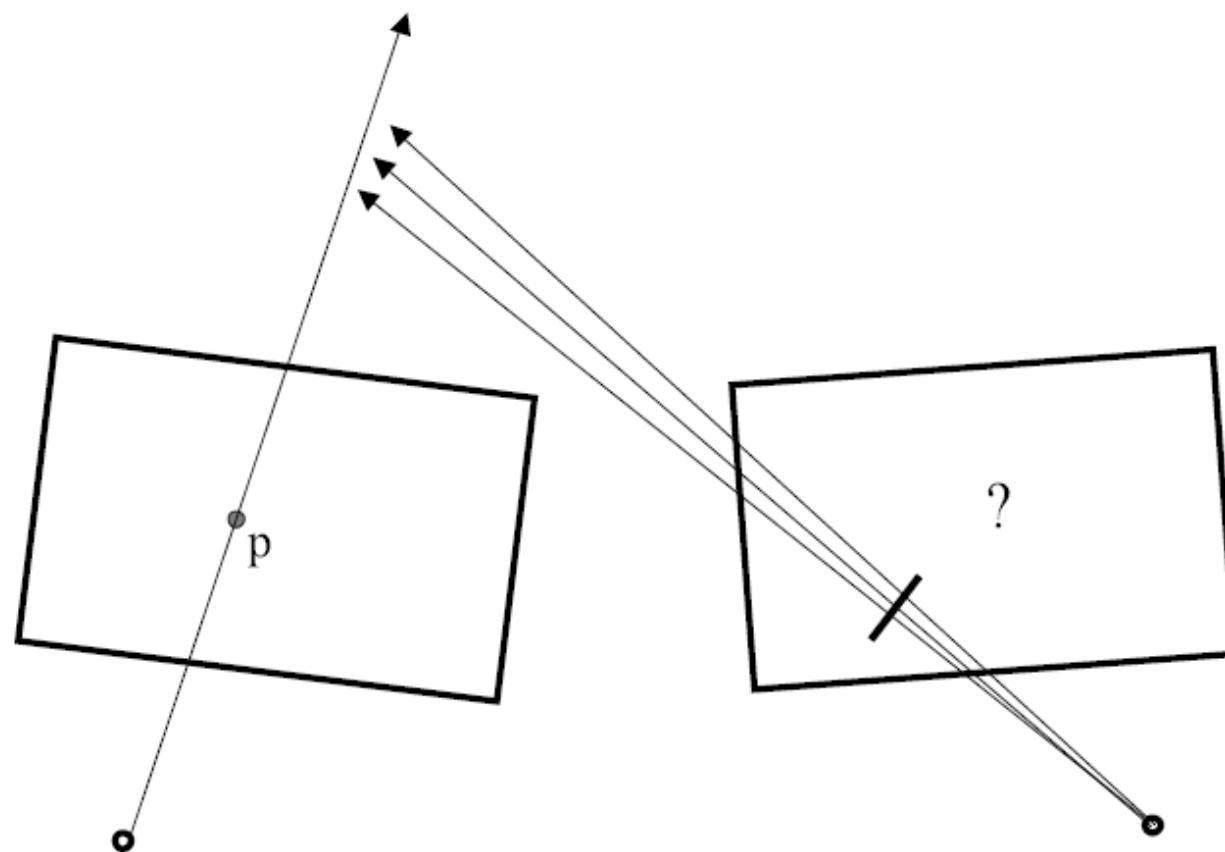

Vs.

Stereo correspondence constraints

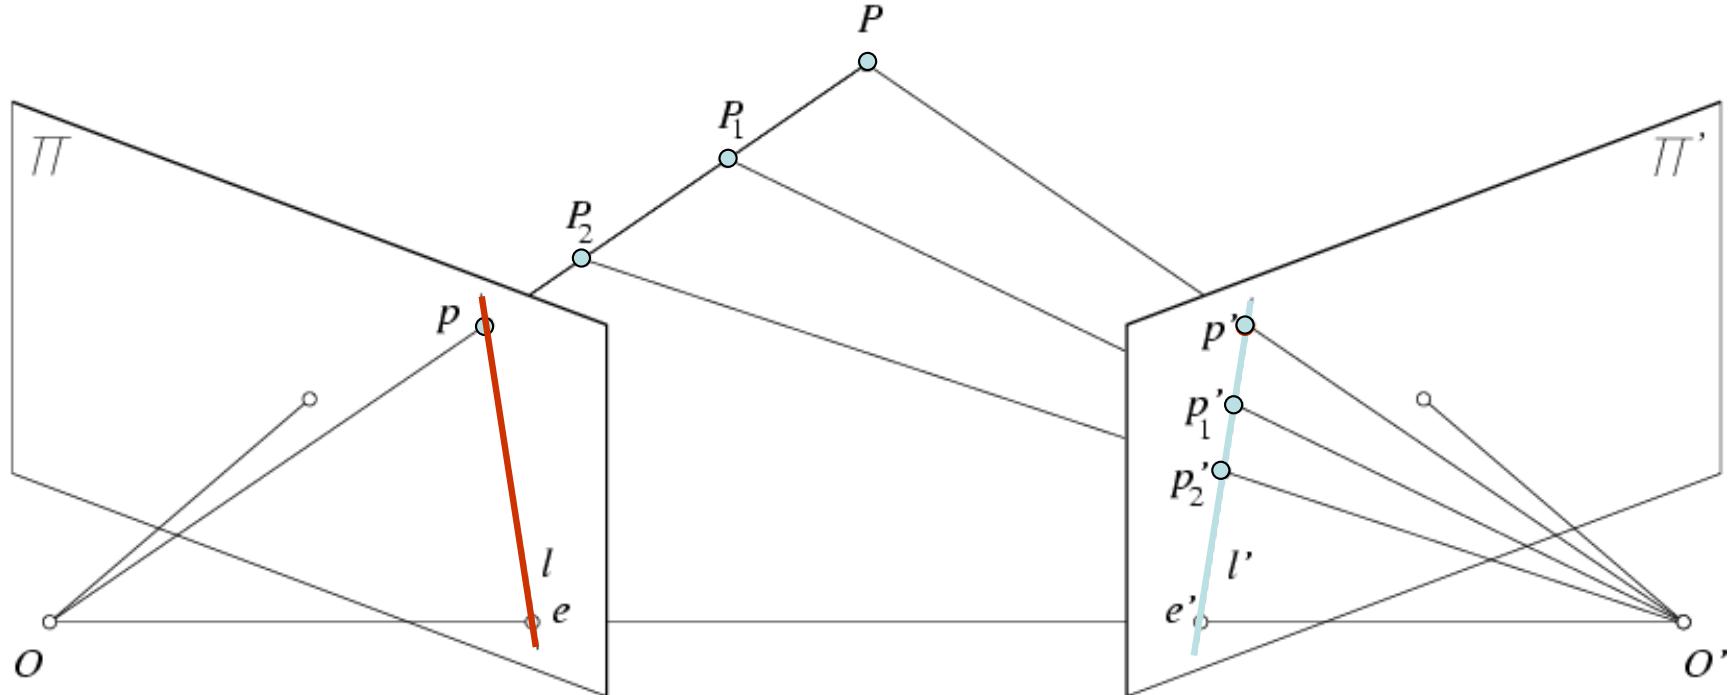

- Given p in left image, where can corresponding point p' be?

Stereo correspondence constraints

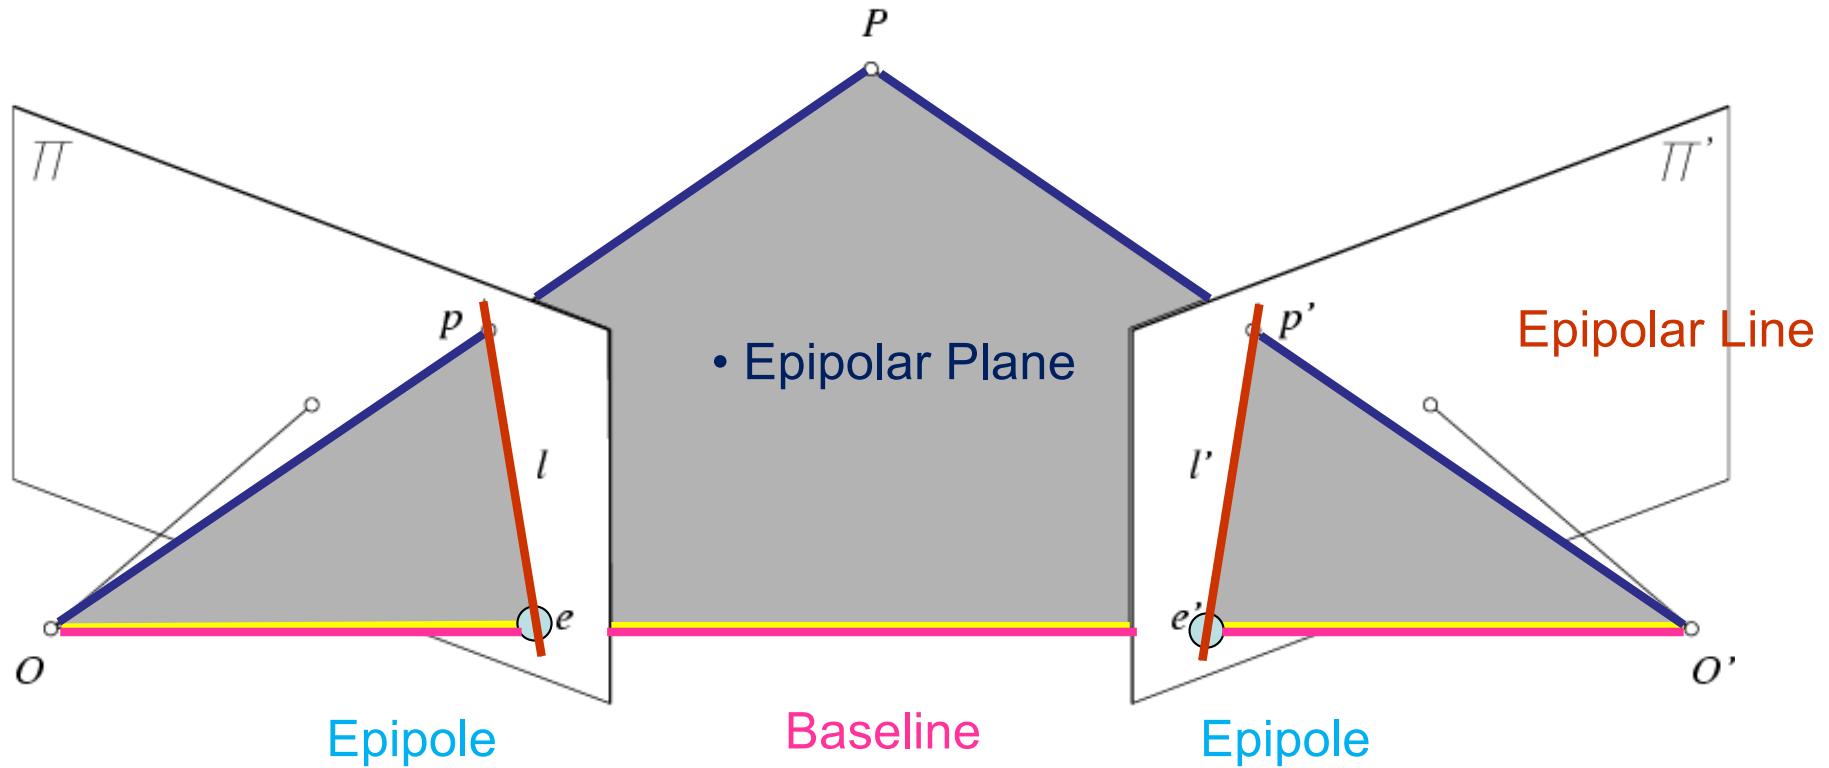

Epipolar constraint

Geometry of two views constrains where the corresponding pixel for some image point in the first view must occur in the second view.

- It must be on the line carved out by a plane connecting the world point and optical centers.

Epipolar geometry

<http://www.ai.sri.com/~luong/research/Meta3DViewer/EpipolarGeo.html>

Epipolar geometry: terms

- **Baseline:** line joining the camera centers
 - **Epipole:** point of intersection of baseline with image plane
 - **Epipolar plane:** plane containing baseline and world point
 - **Epipolar line:** intersection of epipolar plane with the image plane
-
- All epipolar lines intersect at the epipole
 - An epipolar plane intersects the left and right image planes in epipolar lines

Why is the epipolar constraint useful?

Epipolar constraint

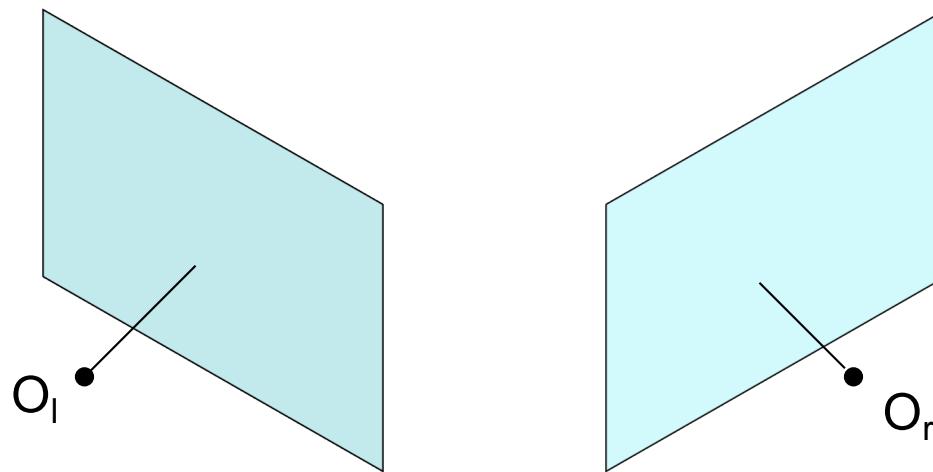

This is useful because it reduces the correspondence problem to a 1D search along an epipolar line.

Example

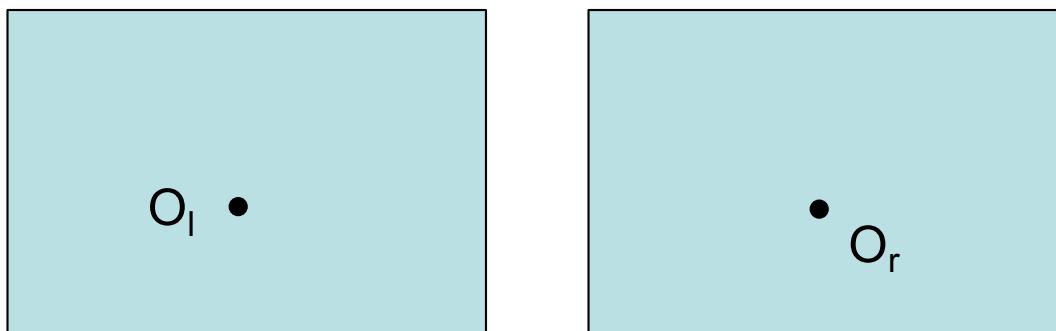

What do the epipolar lines look like?

1.

2.

Example: converging cameras

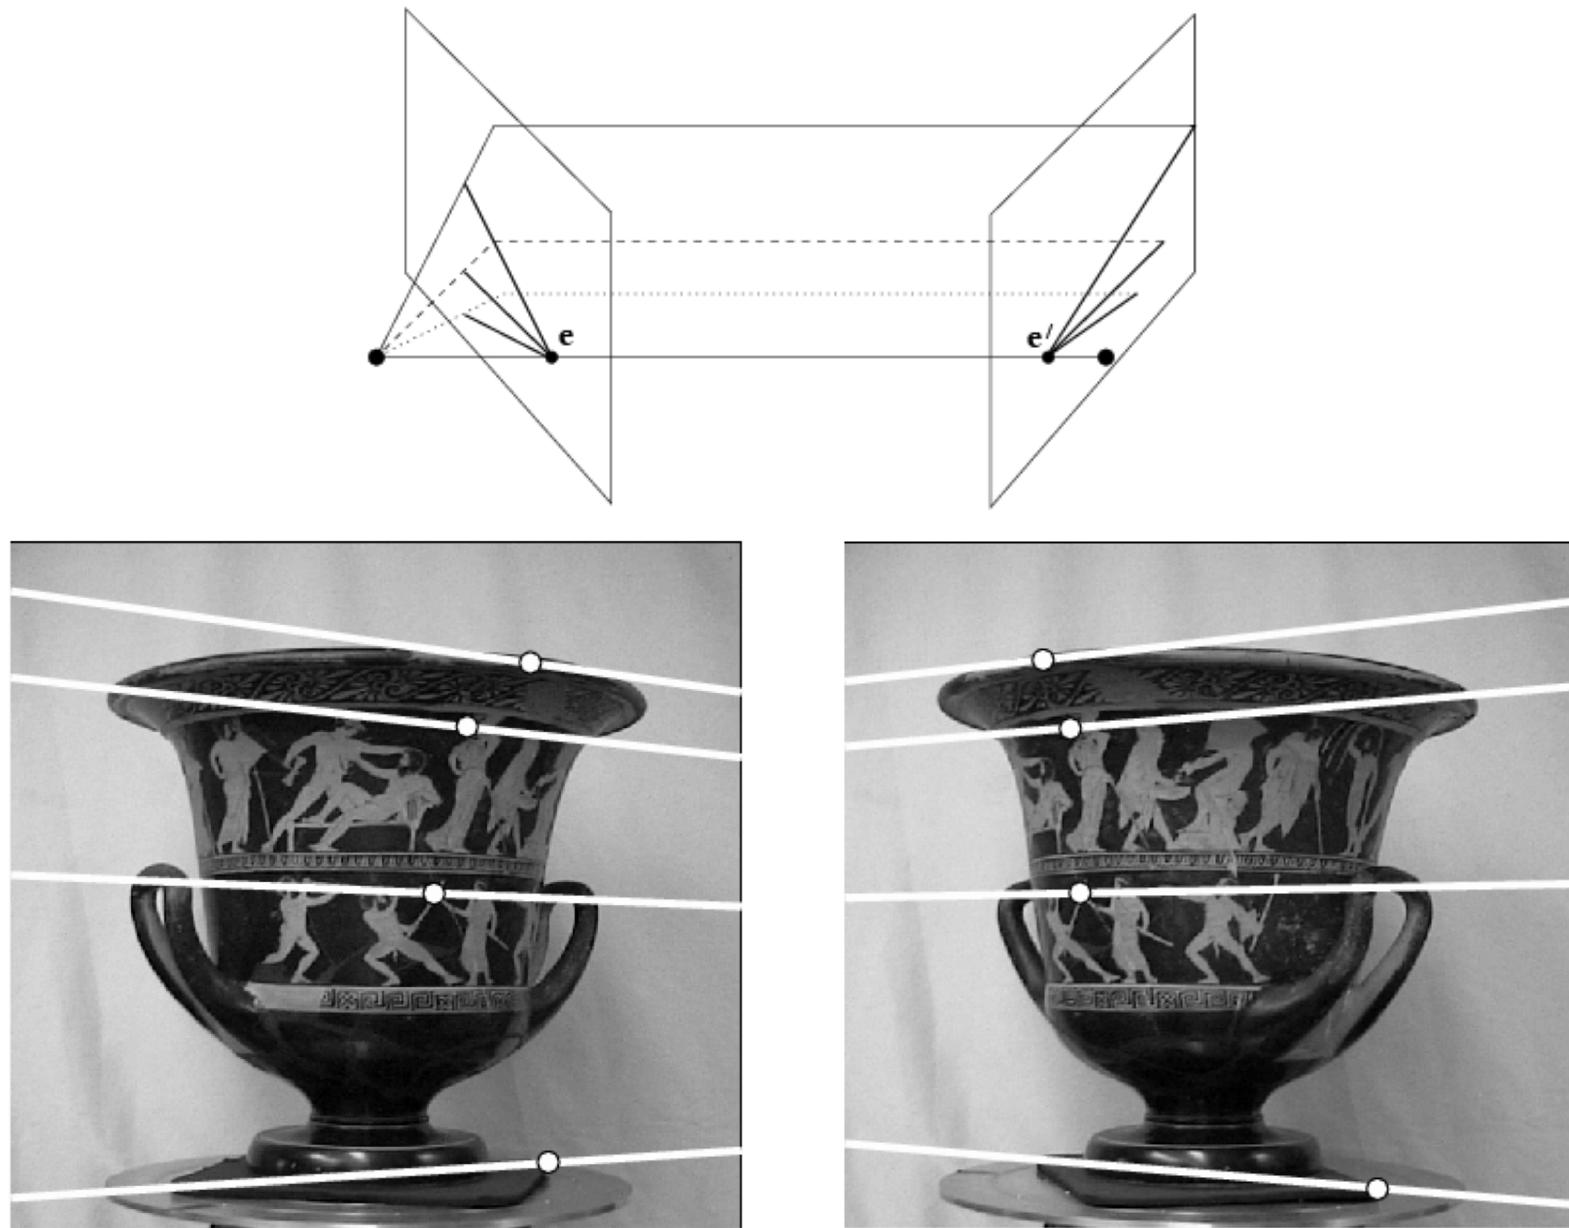

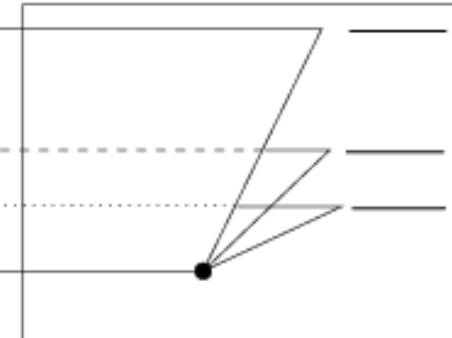

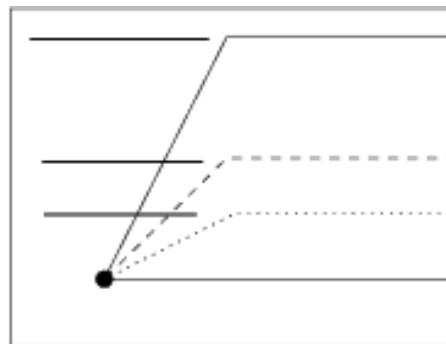

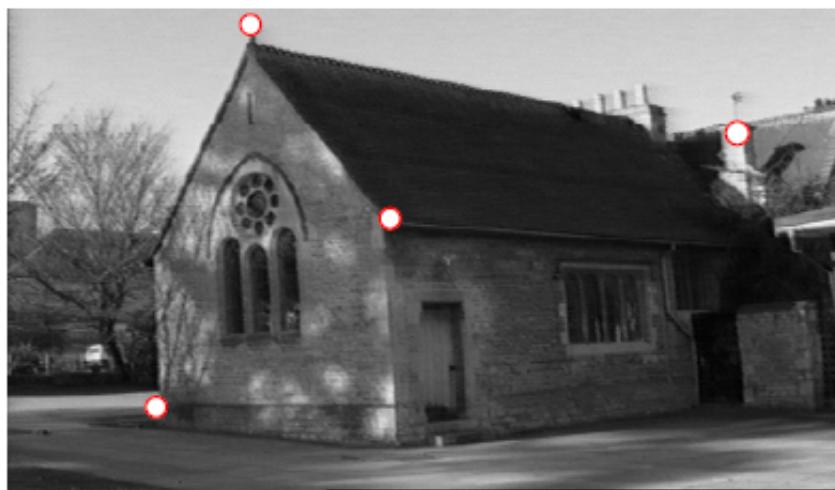

Figure from Hartley & Zisserman

Example: parallel cameras

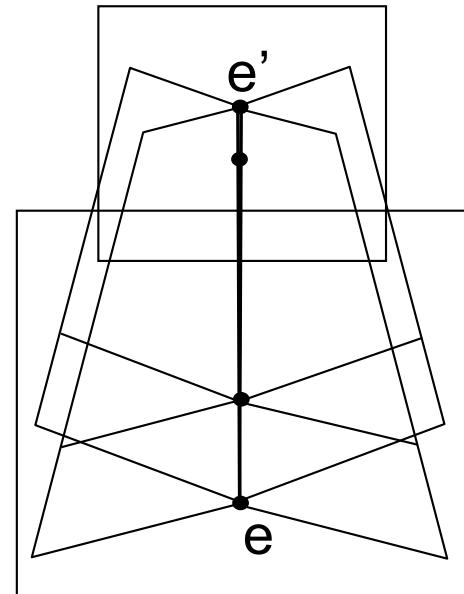

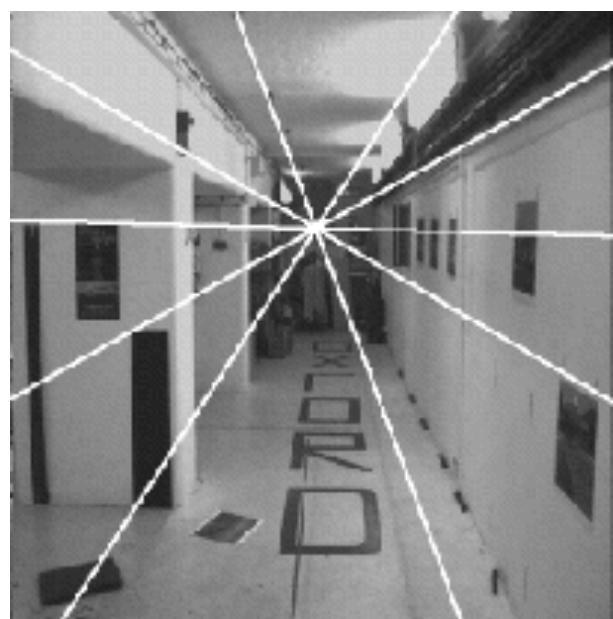

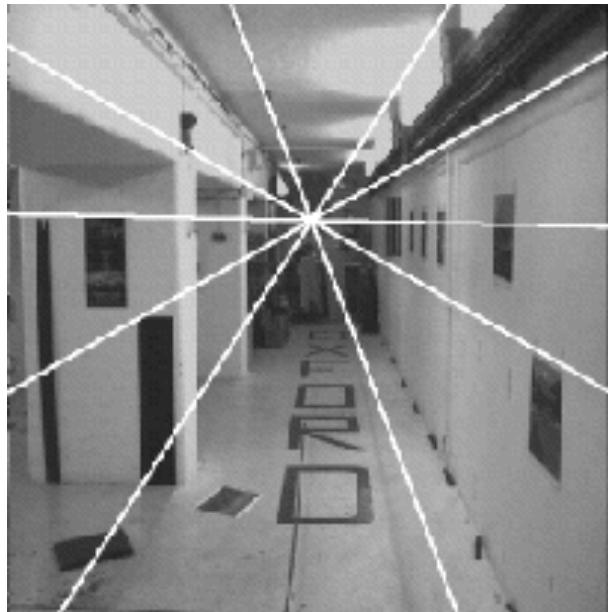

Where are the epipoles?

Example: Forward motion

What would the epipolar lines look like if the camera moves directly forward?

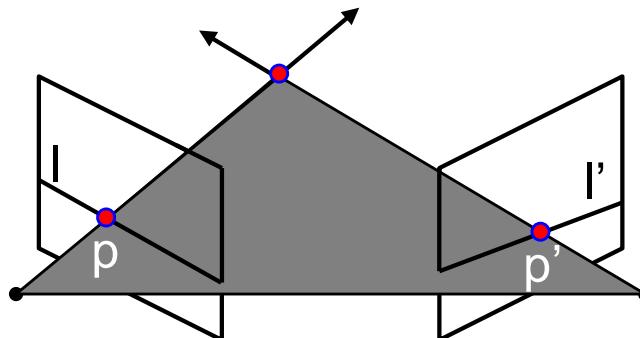

Example: Forward motion

Epipole has same coordinates in both images.
Points move along lines radiating from e :
“Focus of expansion”

Fundamental matrix

Let p be a point in left image, p' in right image

Epipolar relation

- p maps to epipolar line I'
- p' maps to epipolar line I

Epipolar mapping described by a 3×3 matrix F

$$l' = Fp$$

$$l = p'F$$

It follows that

$$p'Fp = 0$$

Fundamental matrix

This matrix F is called

- the “Essential Matrix”
 - when image intrinsic parameters are known
- the “Fundamental Matrix”
 - more generally (uncalibrated case)

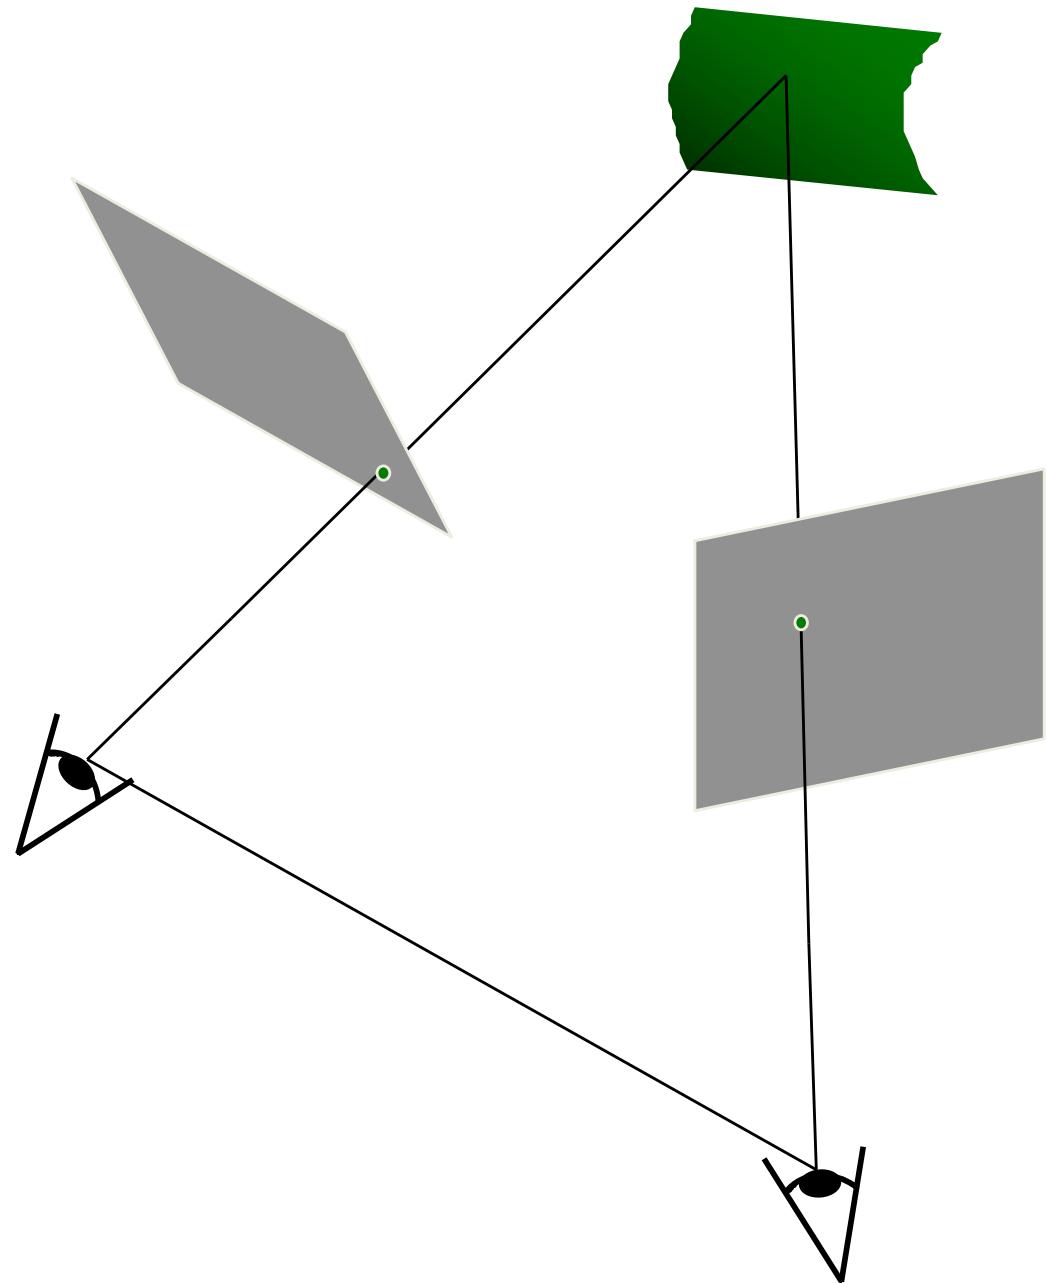

Can solve for F from point correspondences

- Each (p, p') pair gives one linear equation in entries of F

$$p' F p = 0$$

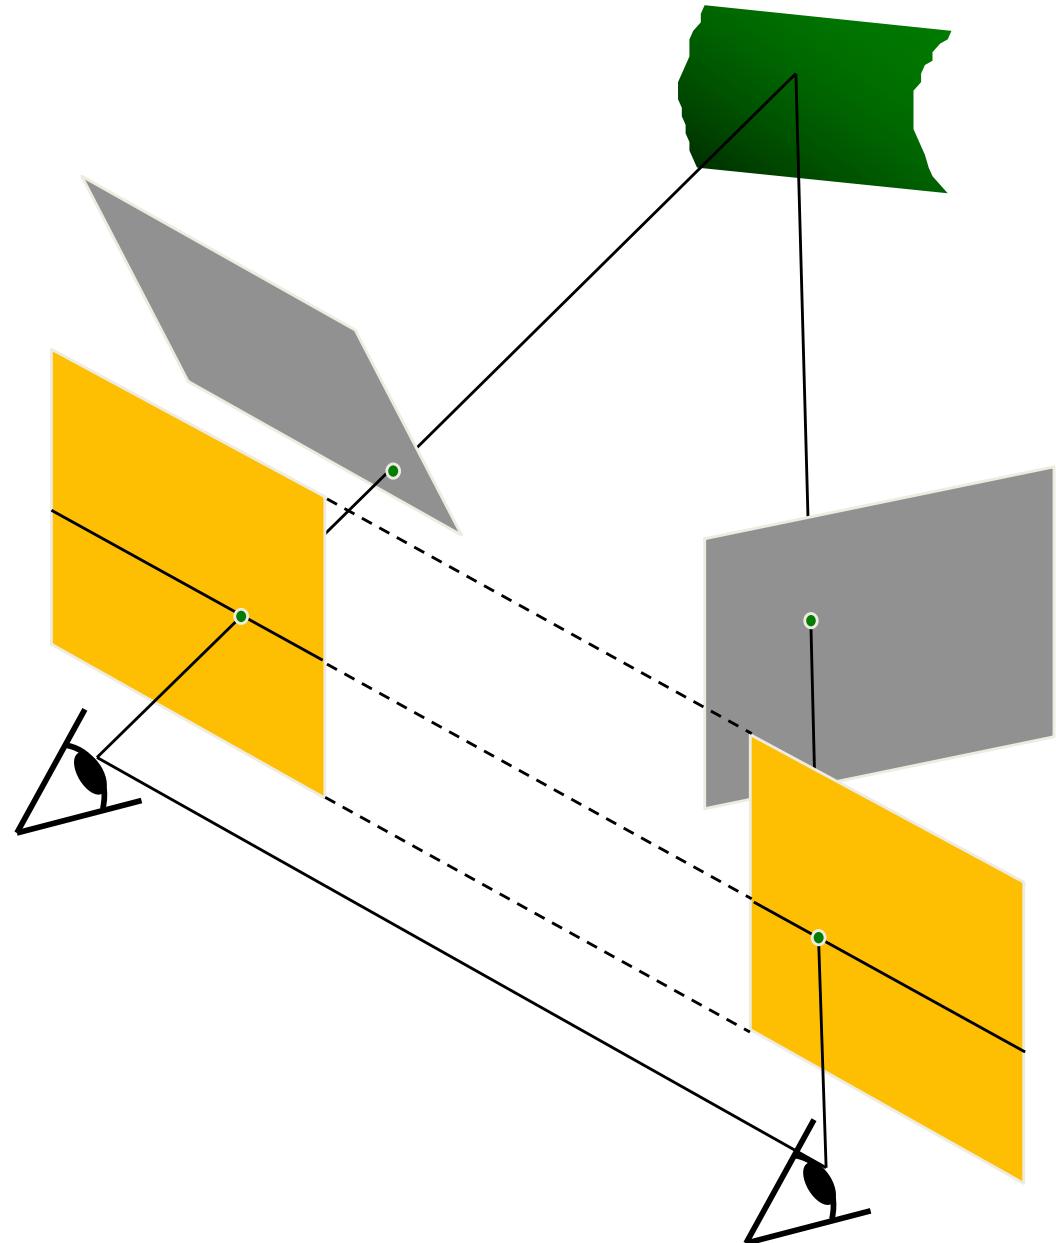

- 8 points give enough to solve for F (8-point algorithm)

Stereo image rectification

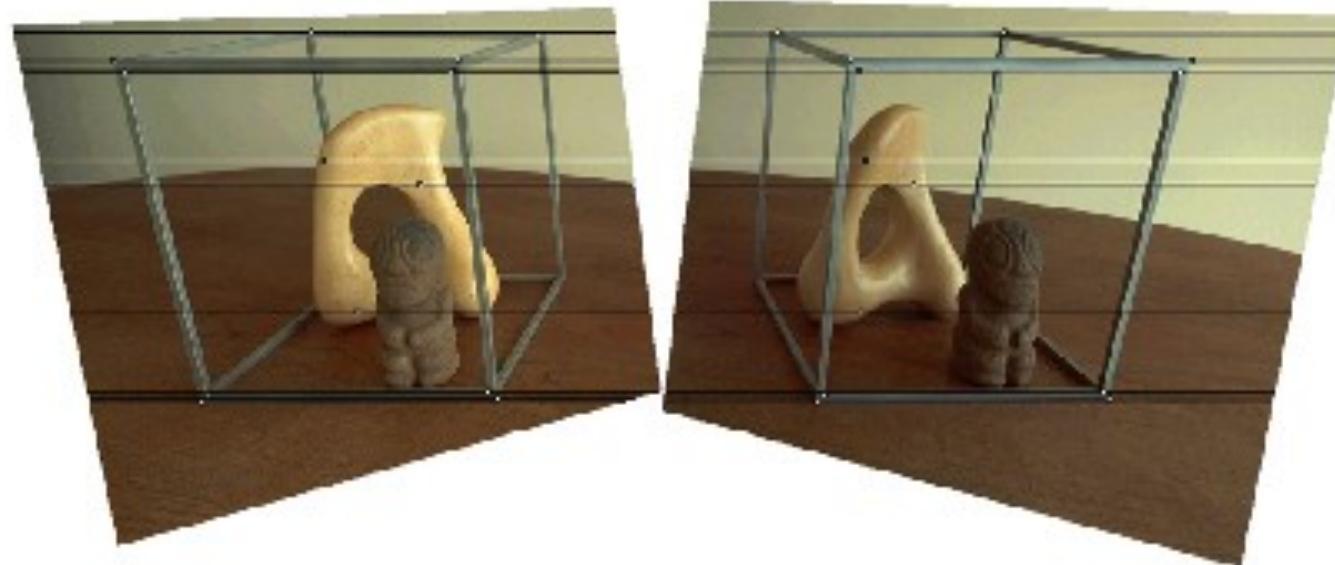

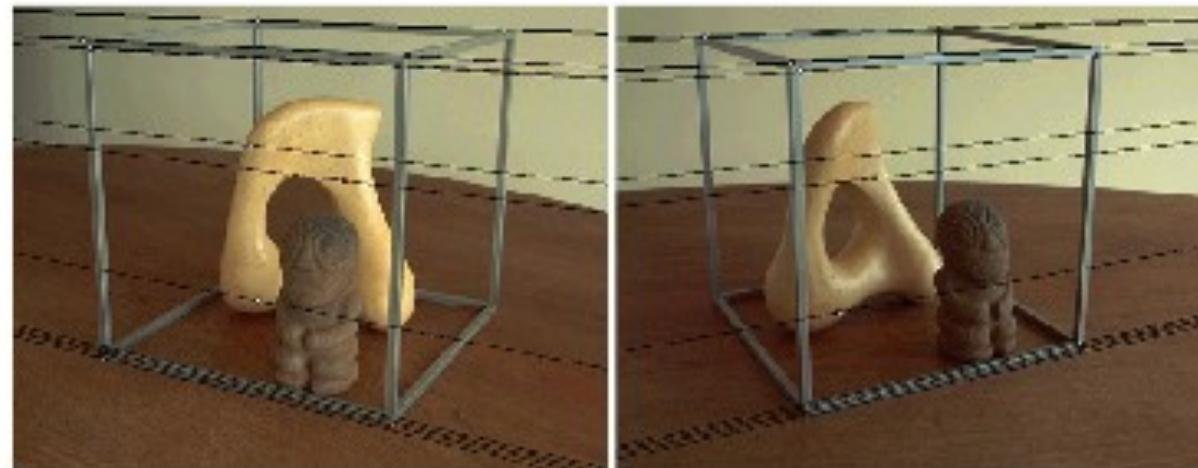

Stereo image rectification

- Reproject image planes onto a common plane parallel to the line between camera centers
 - Pixel motion is horizontal after this transformation
 - Two homographies (3×3 transform), one for each input image reprojection
- C. Loop and Z. Zhang. [Computing Rectifying Homographies for Stereo Vision](#). IEEE Conf. Computer Vision and Pattern Recognition, 1999.

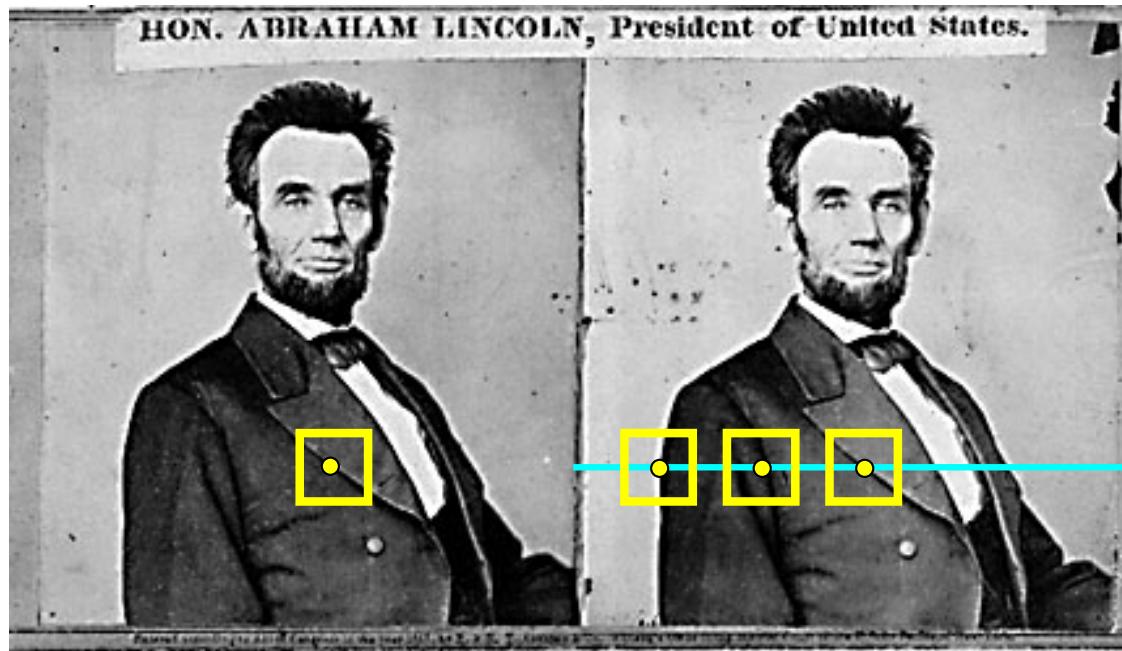

Rectification example

The correspondence problem

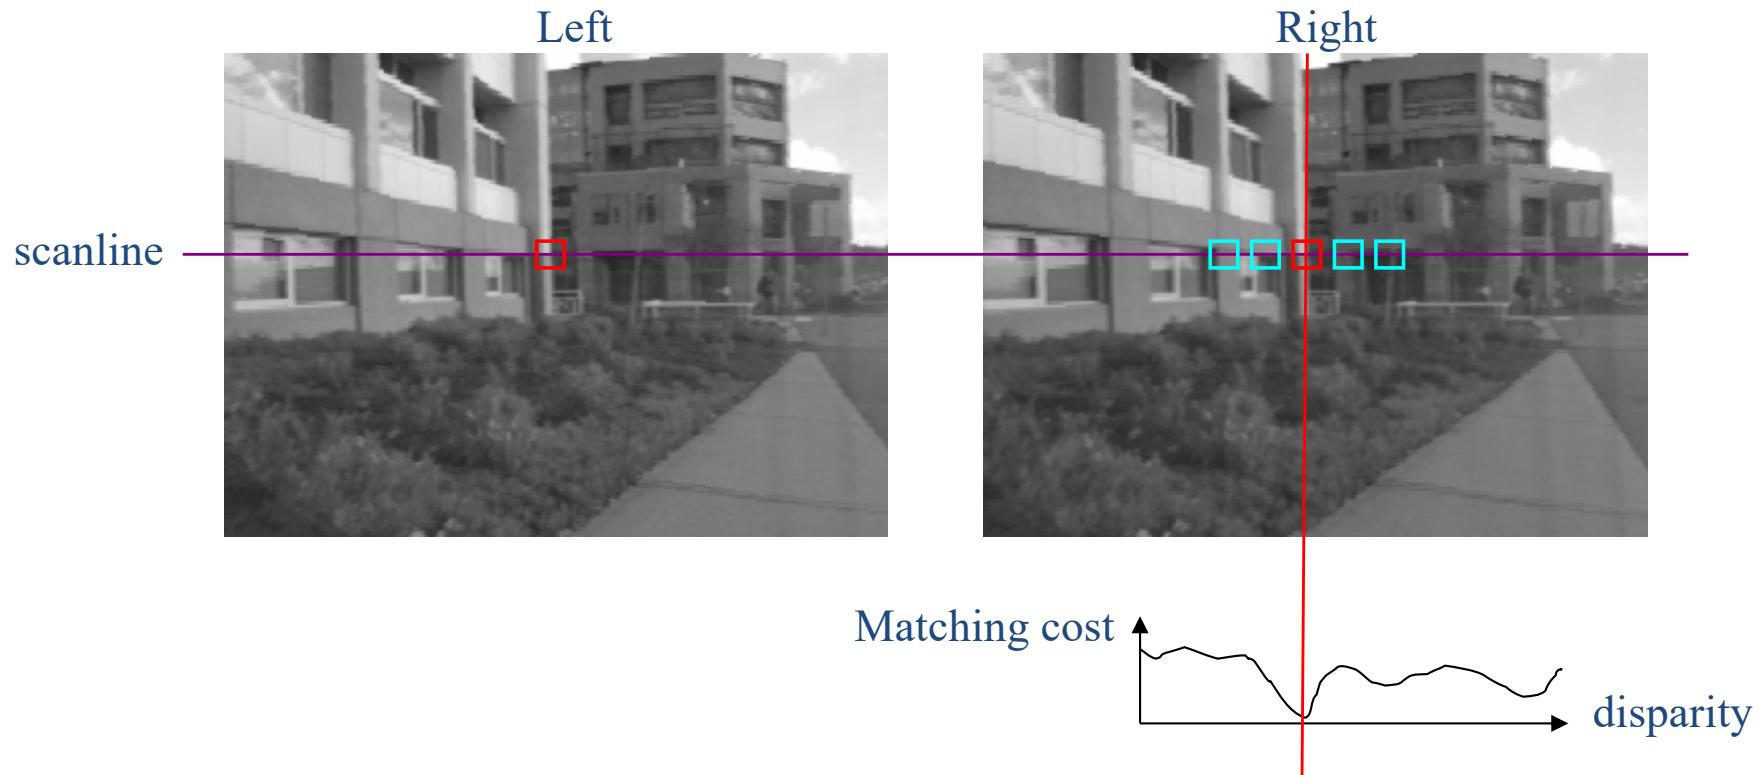

- Epipolar geometry constrains our search, but we still have a difficult correspondence problem.

Basic stereo matching algorithm

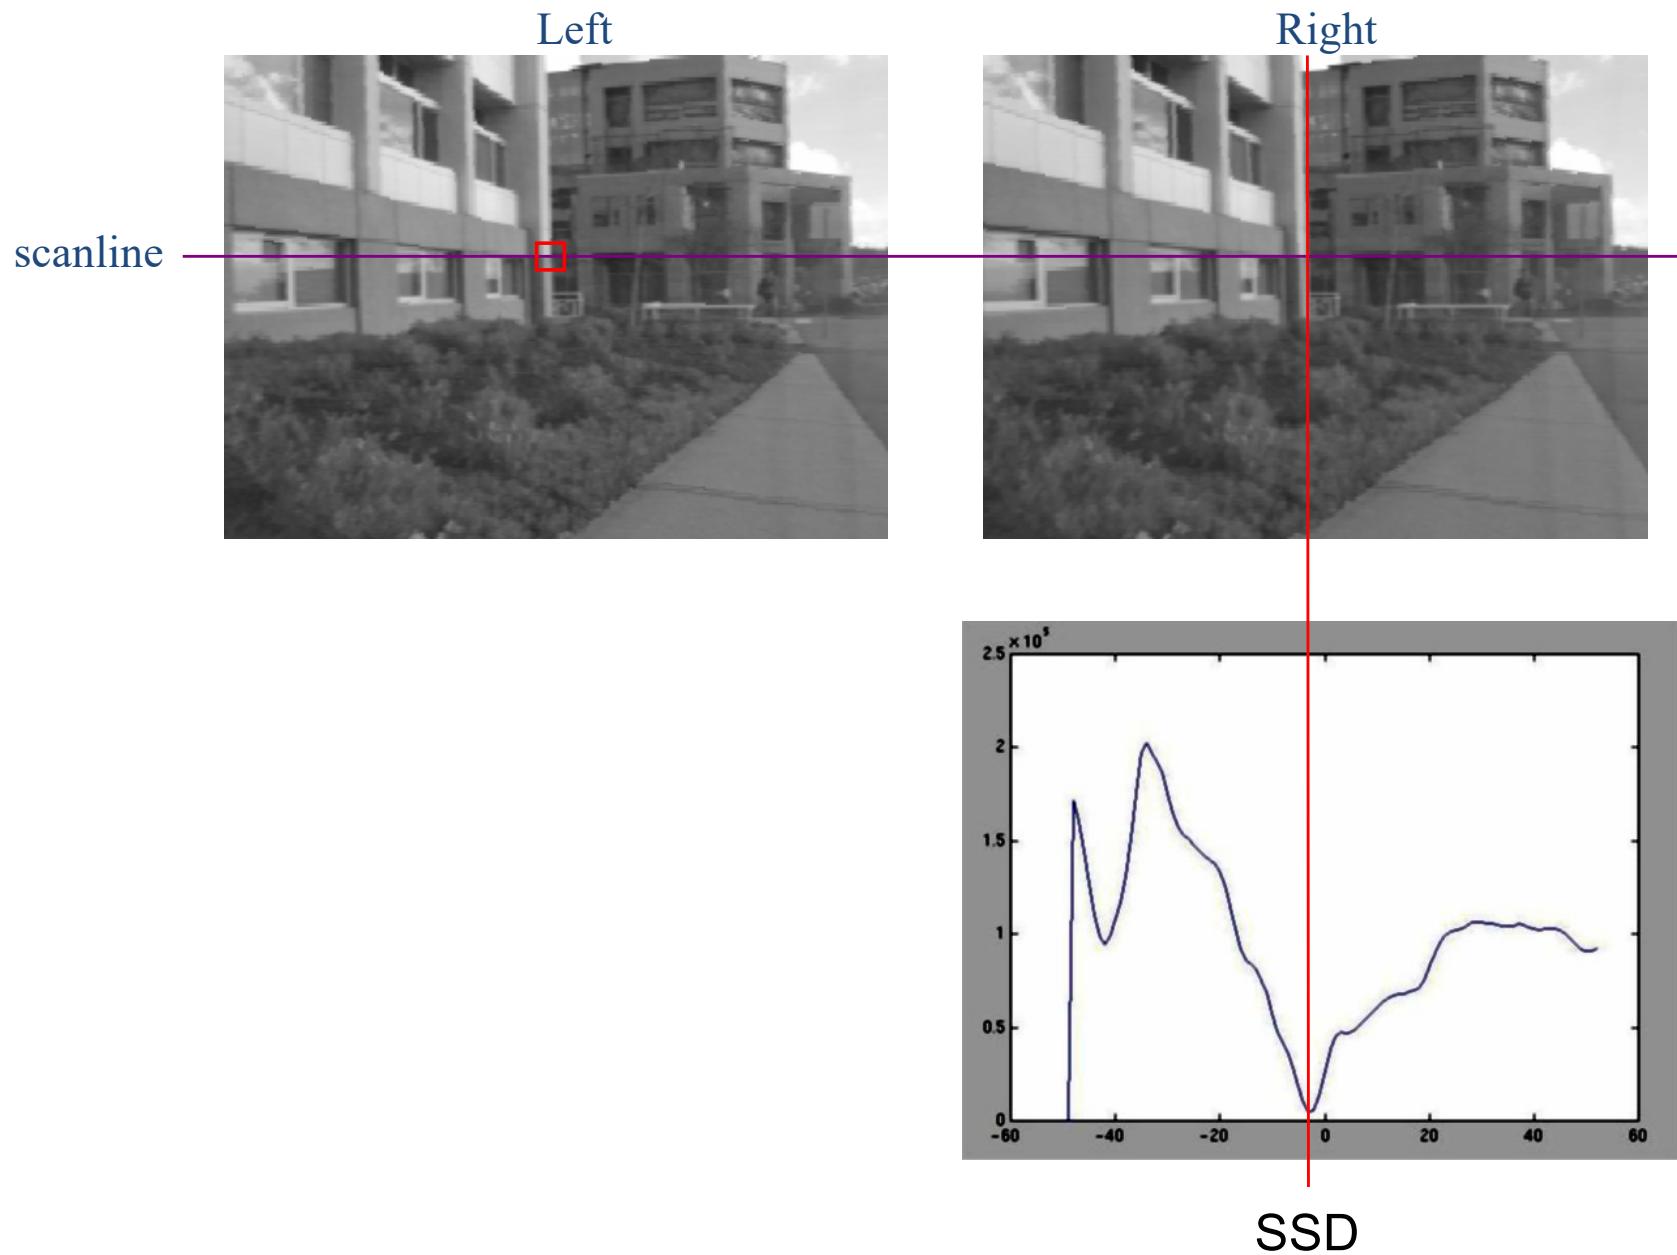

- If necessary, rectify the two stereo images to transform epipolar lines into scanlines
- For each pixel x in the first image
 - Find corresponding epipolar scanline in the right image
 - Examine all pixels on the scanline and pick the best match x'
 - Compute disparity $x-x'$ and set $\text{depth}(x) = fB/(x-x')$

Correspondence search

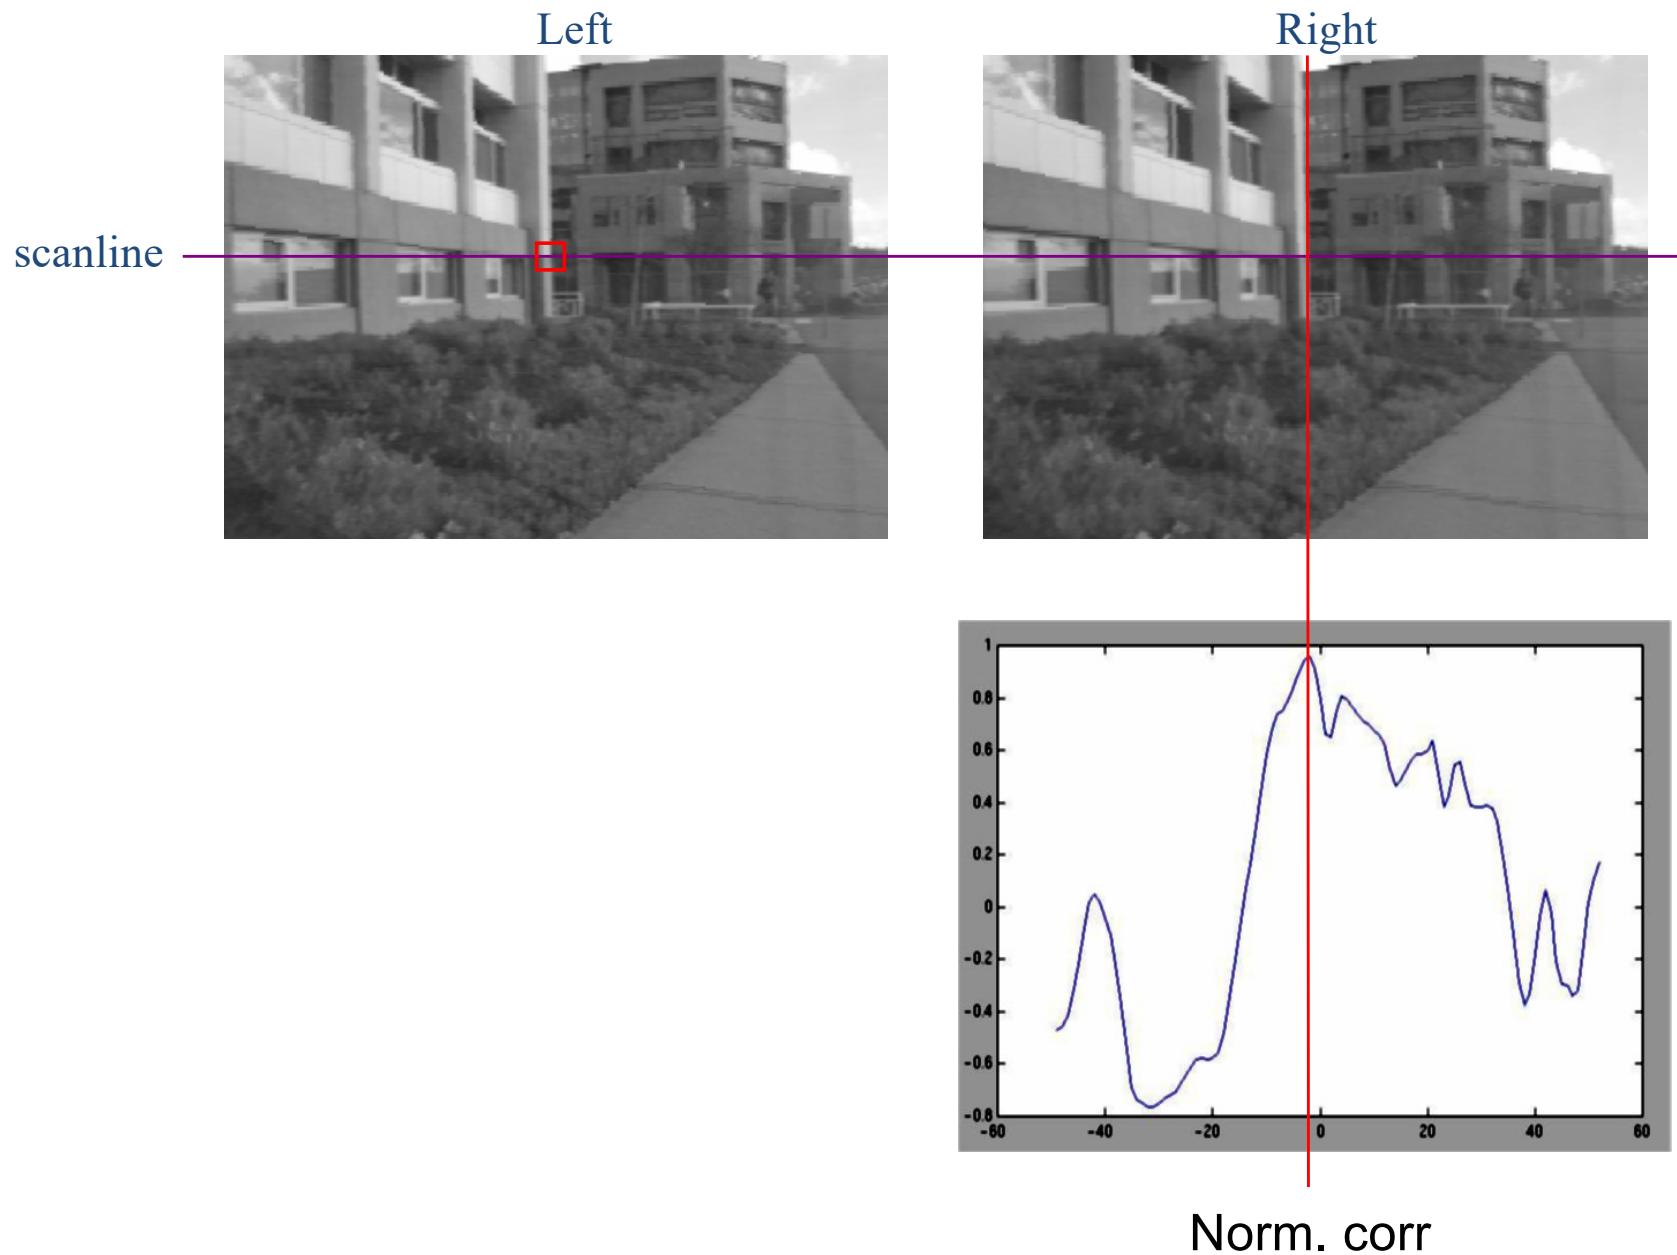

- Slide a window along the right scanline and compare contents of that window with the reference window in the left image
- Matching cost: SSD or normalized correlation

Correspondence search

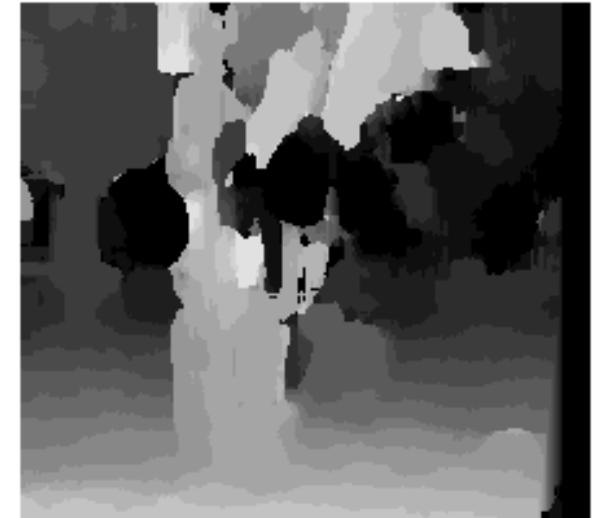

Correspondence search

Effect of window size

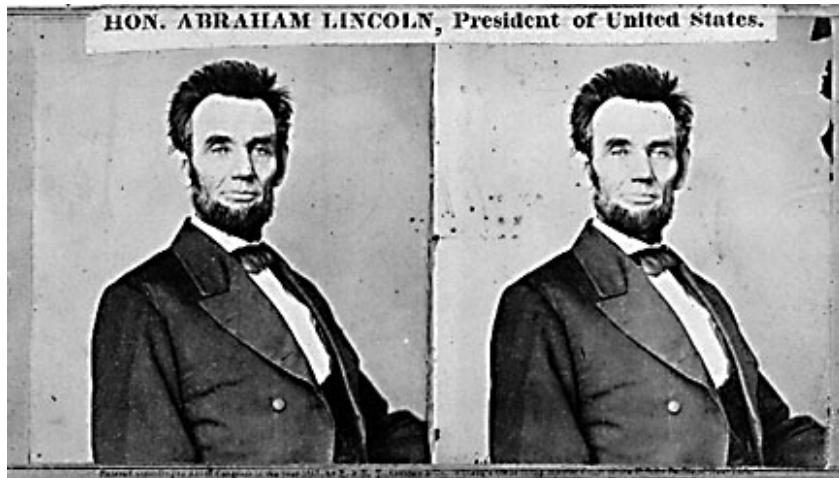

$W = 3$

$W = 20$

- Smaller window
 - + More detail
 - More noise
- Larger window
 - + Smoother disparity maps
 - Less detail

Failures of correspondence search

Textureless surfaces

Occlusions, repetition

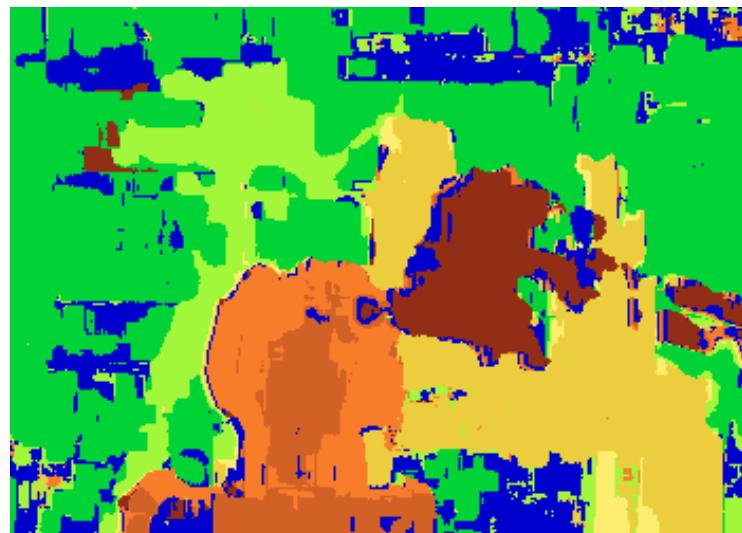

Non-Lambertian surfaces, specularities

Results with window search

Data

Window-based matching

Ground truth

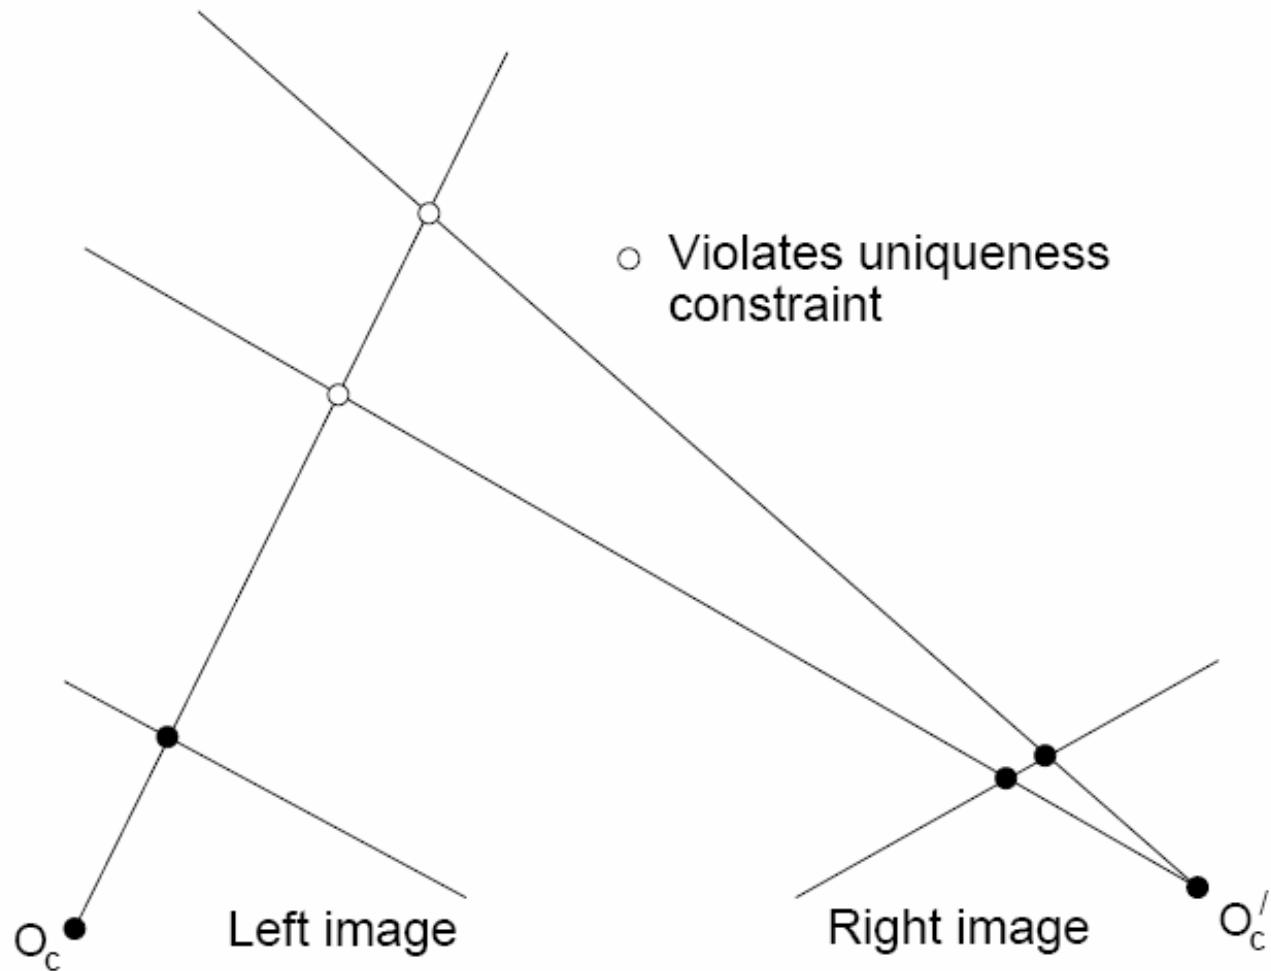

How can we improve window-based matching?

- So far, matches are independent for each point
- What constraints or priors can we add?

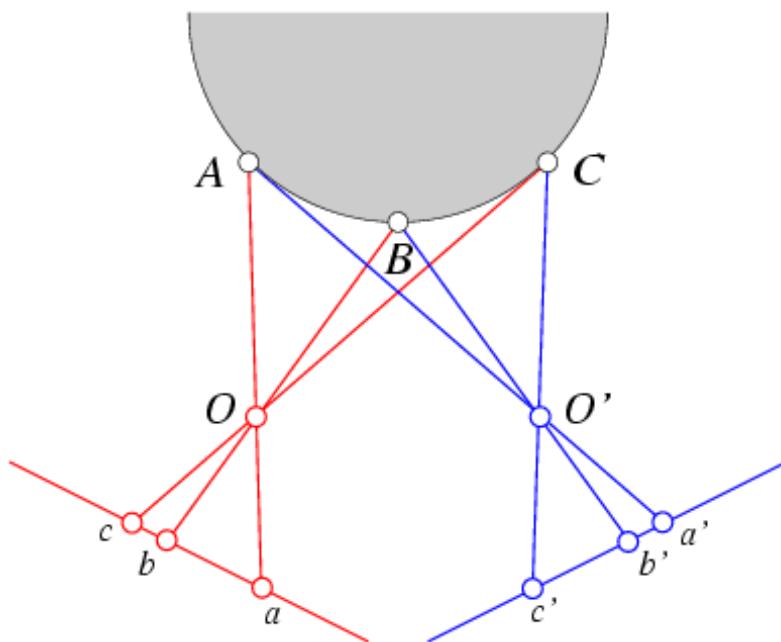

Stereo constraints/priors

- Uniqueness
 - For any point in one image, there should be at most one matching point in the other image

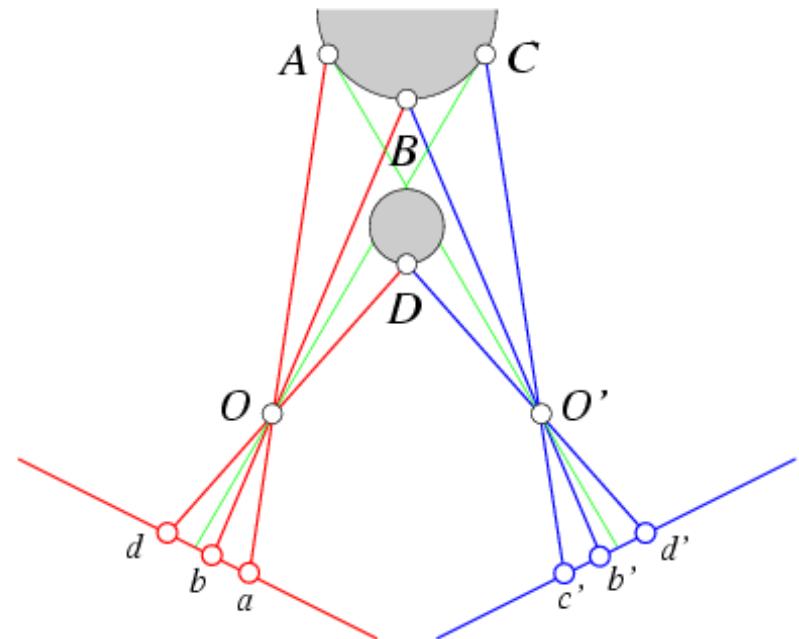

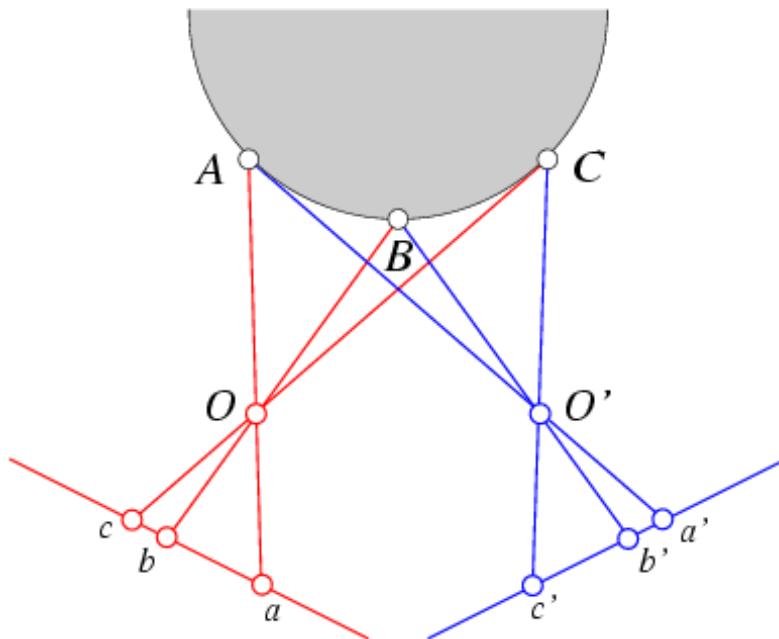

Stereo constraints/priors

- Uniqueness
 - For any point in one image, there should be at most one matching point in the other image
- Ordering
 - Corresponding points should be in the same order in both views

Stereo constraints/priors

- Uniqueness
 - For any point in one image, there should be at most one matching point in the other image
- Ordering
 - Corresponding points should be in the same order in both views

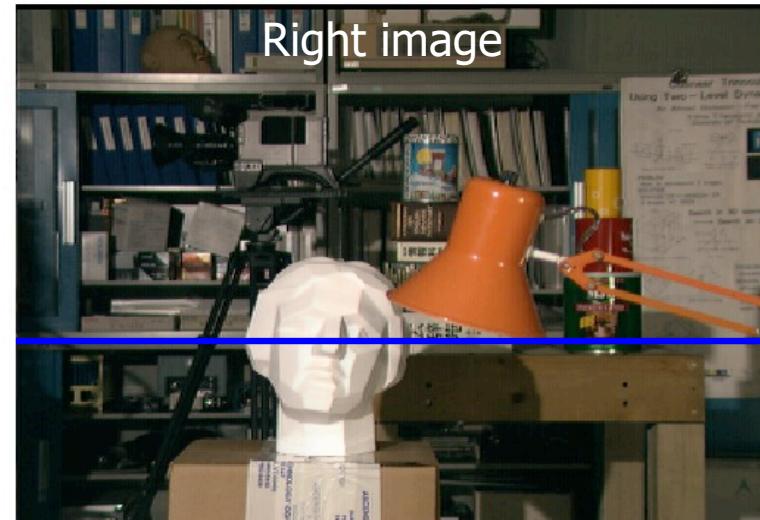

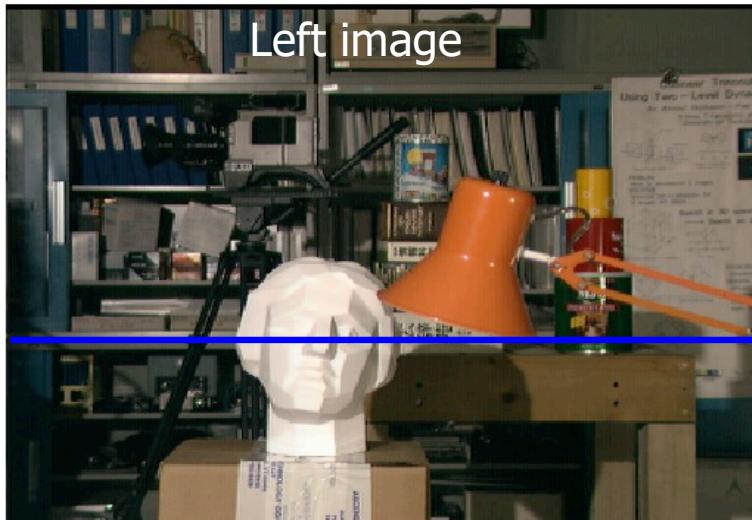

Ordering constraint doesn't hold

Priors and constraints

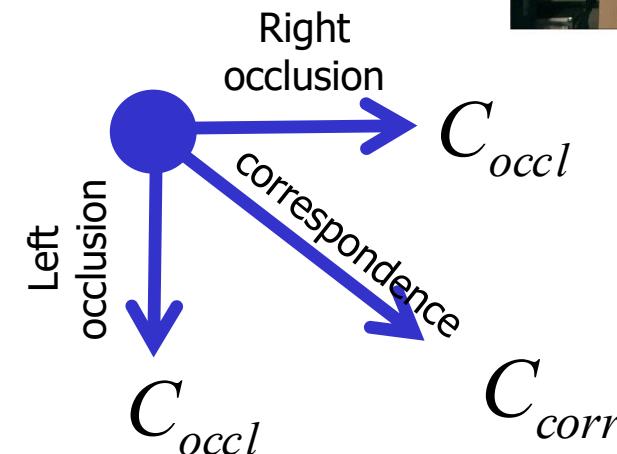

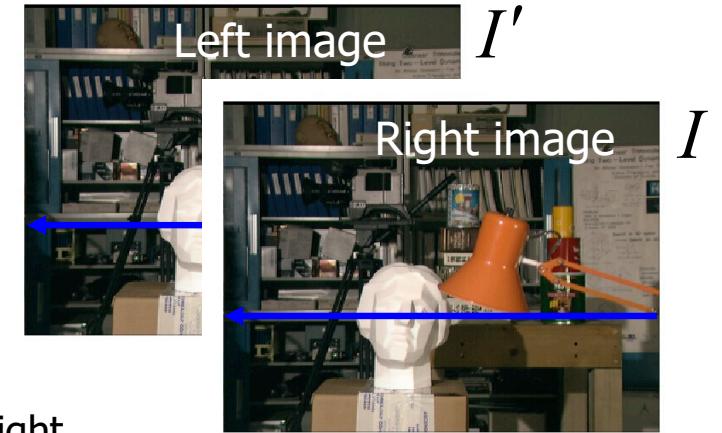

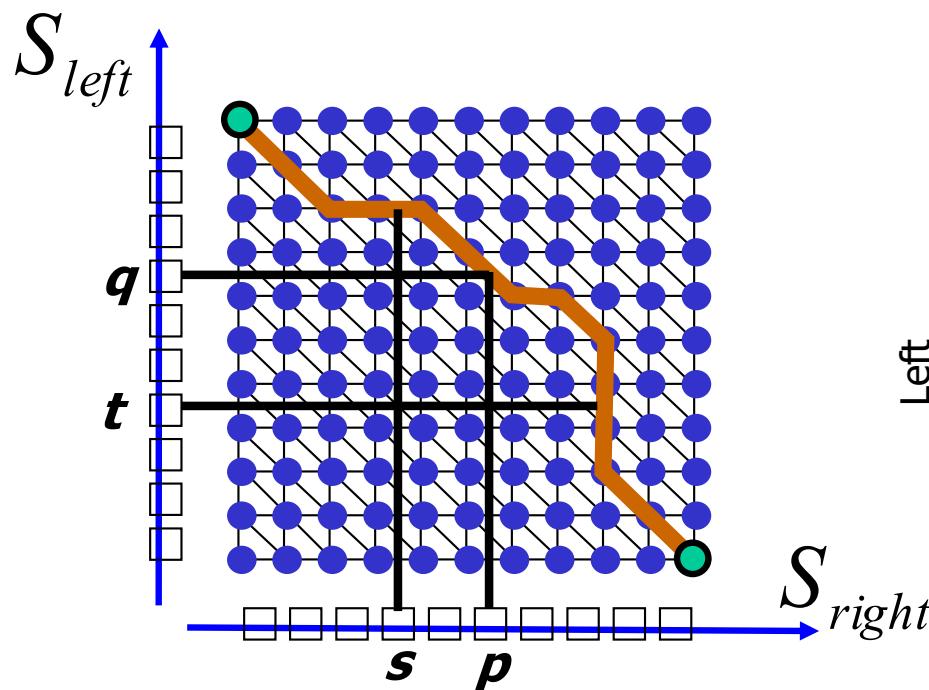

- Uniqueness
 - For any point in one image, there should be at most one matching point in the other image
- Ordering
 - Corresponding points should be in the same order in both views
- Smoothness
 - We expect disparity values to change slowly (for the most part)

Scanline stereo

- Try to coherently match pixels on the entire scanline
- Different scanlines are still optimized independently

“Shortest paths” for scan-line stereo

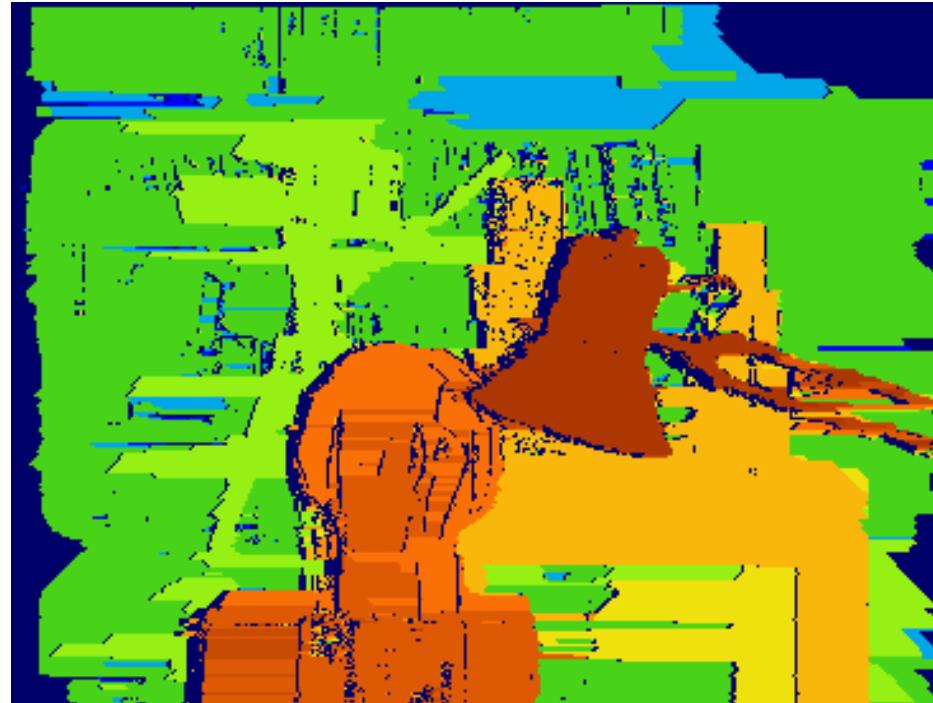

Can be implemented with dynamic programming

Ohta & Kanade '85, Cox et al. '96

Slide credit: Y. Boykov

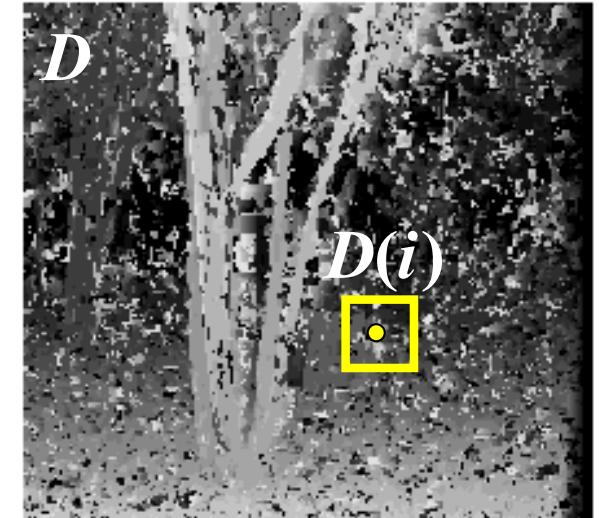

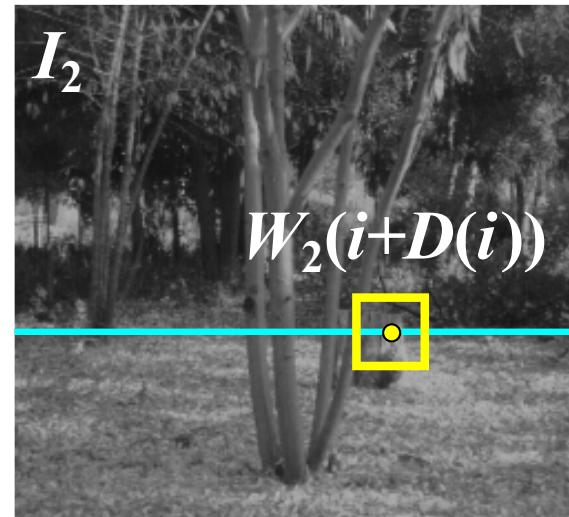

Coherent stereo on 2D grid

- Scanline stereo generates streaking artifacts

- Can't use dynamic programming to find spatially coherent disparities/ correspondences on a 2D grid

Stereo matching as energy minimization

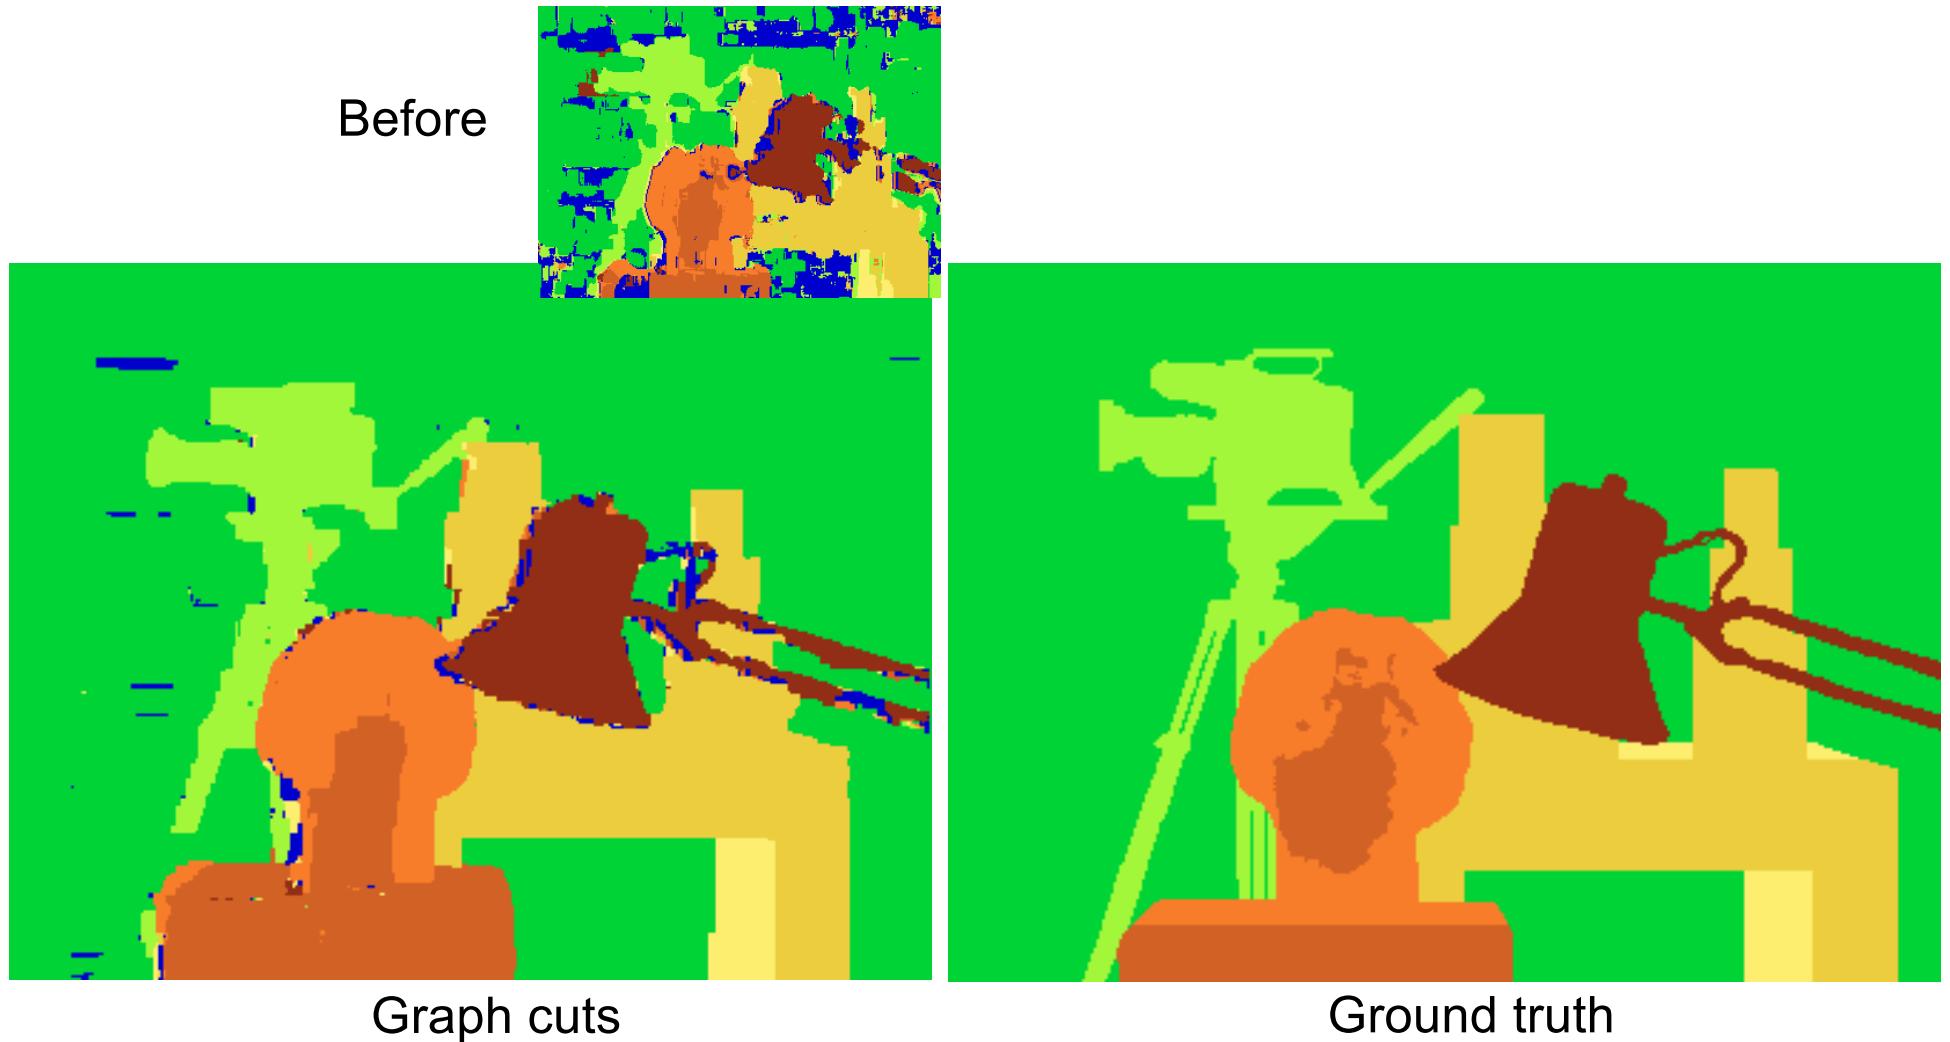

$$E(D) = \underbrace{\sum_i (W_1(i) - W_2(i + D(i)))^2}_{\text{data term}} + \lambda \underbrace{\sum_{\text{neighbors } i, j} \rho(D(i) - D(j))}_{\text{smoothness term}}$$

- Energy functions of this form can be minimized using *graph cuts*

Y. Boykov, O. Veksler, and R. Zabih, [Fast Approximate Energy Minimization via Graph Cuts](#), PAMI 2001

Many of these constraints can be encoded in an energy function and solved using graph cuts

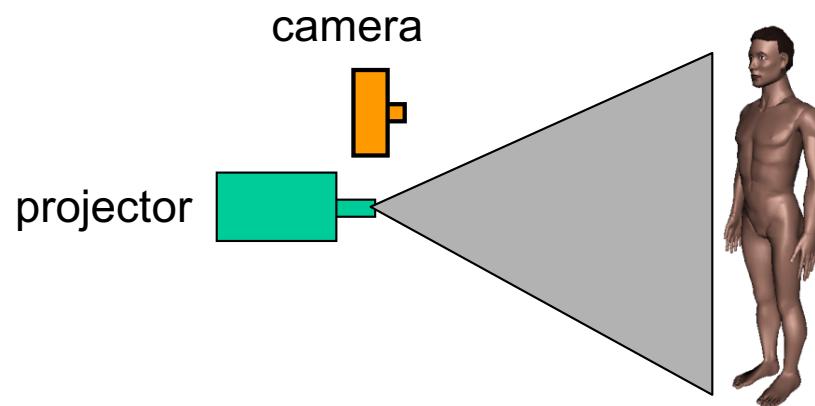

Y. Boykov, O. Veksler, and R. Zabih, [Fast Approximate Energy Minimization via Graph Cuts](#), PAMI 2001

Active stereo with structured light

- Project “structured” light patterns onto the object
 - Simplifies the correspondence problem
 - Allows us to use only one camera

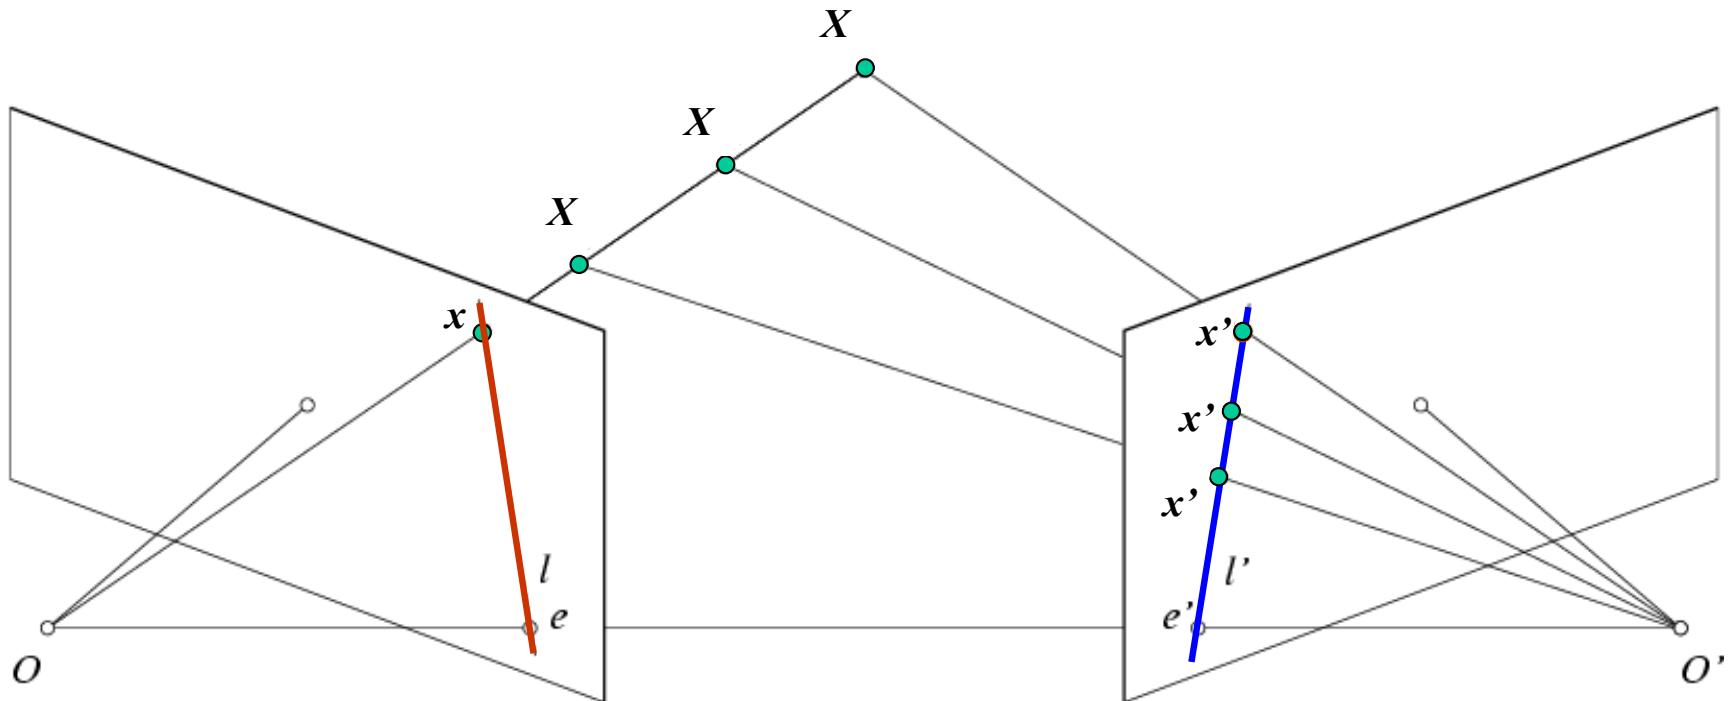

L. Zhang, B. Curless, and S. M. Seitz. [Rapid Shape Acquisition Using Color Structured Light and Multi-pass Dynamic Programming](#). 3DPVT 2002

Kinect: Structured infrared light

Summary: Key idea: Epipolar constraint

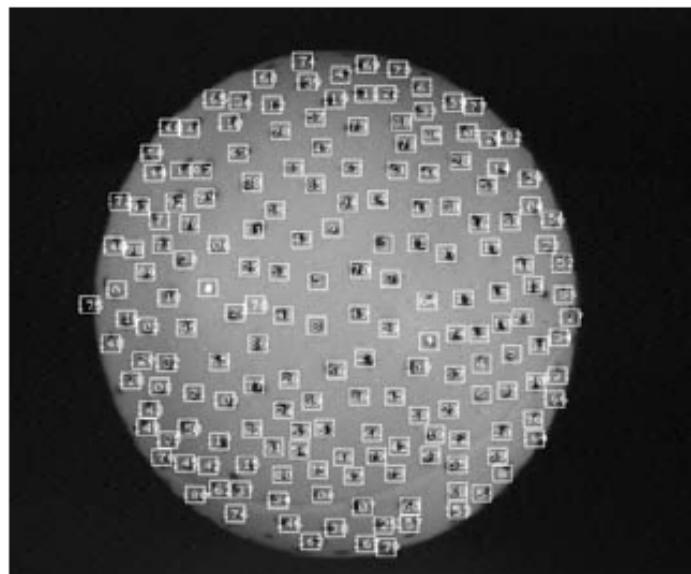

Potential matches for x have to lie on the corresponding line l' .

Potential matches for x' have to lie on the corresponding line l .

Summary

- Epipolar geometry
 - Epipoles are intersection of baseline with image planes
 - Matching point in second image is on a line passing through its epipole
 - Fundamental matrix maps from a point in one image to a line (its epipolar line) in the other
 - Can solve for F given corresponding points (e.g., interest points)
- Stereo depth estimation
 - Estimate disparity by finding corresponding points along scanlines
 - Depth is inverse to disparity
